NATURAL HISTORY

Vol. 94, No. 1, January 1985

American Museum of Natural History
Robert G. Goelet, President
Thomas D. Nicholson, Director

4 Ancestors *Richard G. Klein*
Breaking Away

10 The Human Strategy *Stanley A. Freed and Ruth S. Freed*
"One Son Is No Sons"

16 This View of Life *Stephen Jay Gould*
The Sinister and the Trivial

30 The Living Museum *Douglas J. Preston*
The Glowing Avalanche

34 This Land *Robert H. Mohlenbrock*
Oak Creek Canyon, Arizona

38 Birds of Fire *David E. Manry*
After a grassland burn, the bald ibises feast on fresh-roasted insects.

46 The Little Foxes *J. David Henry*
It's time for foxes to go a-courtin' again.

58 So Grows the Tree *Jeffry B. Mitton*
Alpine trees, like today's yuppies, are strongly molded by designer genes.

66 Bringing the Captain Back to the Bay *Dorothy Harley Eber*
The nineteenth-century Inuit called the whaling captain a shaman because he made images "appear just like that, out of a piece of paper."

76 Books in Review *Wilcomb E. Washburn*
Toward Indian Nationhood

82 Celestial Events *Thomas D. Nicholson*
Venus Shows Off

84 Sky Reporter *Stephen P. Maran*
The Comet That Wouldn't Die

92 A Matter of Taste *Raymond Sokolov*
A Delectable Drupe

97 The Natural Moment *Photographs by Cynthia D'Vincent*
The Long Goodbye

100 Additional Reading

Breaking Away

Even in its infancy, modern humanity displayed a talent for innovation

by Richard G. Klein

Nearly a century ago, archeologists working in Europe learned that the Neanderthals and their anatomically modern successors, the Cro-Magnons, made very different kinds of artifacts. The standard nomenclature reflects the distinction: Neanderthal artifacts are placed in the Middle Paleolithic cultural stage, while those of the Cro-Magnons are placed in the succeeding stage, called the Upper Paleolithic. The transition occurred between 40,000 (or perhaps before) and 35,000 years ago. Some specialists believe the Upper Paleolithic culture in Europe developed out of the local Middle Paleolithic, possibly at different times in different places; others argue that the Upper Paleolithic was an intrusive replacement. The issue is tied to the question of whether European Cro-Magnons evolved from local Neanderthals or whether they evolved somewhere else and then spread to Europe, displacing or, by interbreeding, absorbing the Neanderthal population.

Proponents of the idea that the Cro-Magnons and the Upper Paleolithic intruded into Europe have long pointed to evidence that both anatomically modern people and Upper Paleolithic culture appeared earlier in the Near East than in Europe. Recent discoveries in sub-Saharan Africa indicate that modern people may have appeared there even earlier. In addition, the African Middle Stone Age, broadly similar to what in Europe and the Near East is called the Middle Paleolithic, was replaced at least 35,000 or 40,000 years ago by the Later Stone Age, comparable in important ways to the Upper Paleolithic. To assess these major arguments, however, one must first understand the extent to which the two cultural stages differ.

At least three major points of contrast may be explored through archeology: the types of artifacts produced, the forms of environmental exploitation, and the size of human populations. To compare artifacts, archeologists analyze assemblages—the complete sets of artifacts found at different sites. The percentages of different types of tools in an assemblage, for example, may be more significant for characterizing or identifying a culture than the presence of one particular tool.

For Africa, the differences in artifact types are still being worked out, since few sites from the beginning of the Later Stone Age have been excavated and described. However, the differences are well established in Europe and the Near East. Middle Paleolithic assemblages tend to be dominated by stone flakes on which one or more edges have been retouched by chipping to form tools known as sidescrapers, points, denticulates, notches, and so forth. In contrast, Upper Paleolithic assemblages tend to contain a much higher proportion of elongated flakes, which archeologists call blades. These are frequently modified into tool types known as end scrapers and burins. End scrapers and burins have been found in Middle Paleolithic assemblages, but they are rare and are often less carefully made.

What is more striking is that Middle Paleolithic assemblages lack easily identifiable types of bone artifacts, which are present in the Upper Paleolithic. A similar contrast exists in Africa. And not until the Upper Paleolithic or Later Stone Age do items appear that can be unequivocally termed art objects and personal ornaments. The "invention" of art was perhaps tied to recognition that bone and related materials such as ivory, antler, and shell could be carved, polished, or otherwise shaped into myriad forms. These ma
als were the media for most of the ear
known art, although some artistic exp
sion is found in clay and on rock surfa
Perishable materials, such as wood
leather, were probably also used. Conc
ably, there were artists in preceding
who confined their work to perishable
terials; more likely, earlier people did
produce art as we know it.

Middle Paleolithic and Middle St
Age artifact assemblages also vary litt
space and over time. Contemporane
assemblages from regions as far apar
France and the Ukraine tend to con
basically the same artifact types, as do
semblages from separate parts of Afr
What variation there is can be largely
cribed to differences in local stone
material or in the precise activities car
on at different sites (for example, m
food preparation at one site, more we
working at another). Similarly, there is
tle indication of temporal change wit
the Middle Paleolithic or Middle St
Age—even assemblages separated
tens of thousands of years tend to be f
damentally alike.

In contrast, contemporaneous Up
Paleolithic or Later Stone Age artifact
semblages often differ markedly, e
when they come from neighboring
gions, and change through time is c
matic. These variations have led archeo
gists to recognize a multiplicity of Up
Paleolithic cultures, each with an aver
duration of only a few thousand years.
parently these peoples had an ability to
novate and to adapt to local circumstan
that was lacking in their predecessors.

Like those who came before them,
per Paleolithic and Later Stone Age p
ple made their living by hunting and ga

E·NEW·SCIENCE·OF·LUXURY

Chrysler turbocharges the LeBarons. Feel the power of a V-8 with the efficiency of a 4-cylinder.

This is the new science of luxury. It is made possible by a new breed of turbocharger. A water-cooled turbo that spins at speeds of thin air and delivers the power you want for acceleration, more for efficiency, resulting in comfort and luxury.

You have never driven a car like this before. The 1985 turbocharged Chrysler LeBarons are the first series of cars to combine luxury, 6 passenger room, front wheel drive and the option of turbocharging to give the power of a V-8 with the fuel efficiency of a 4-cylinder. And because this is Chrysler engineering at its finest, you enjoy the reassurance of protection. Your engine, drive-train and even your turbo are backed by a 5-year or 50,000-mile Protection Plan* while outer body rust through is covered for the same period.

Naturally, the many luxuries for which LeBaron is known are still standard, and Mark Cross leather is available as the final luxury.

All cars transport you. The turbocharged Chrysler LeBaron Series moves you—like no other cars in America, Europe or Japan. Buckle up for safety. 23 HWY EST MPG** 20 CITY EST MPG**

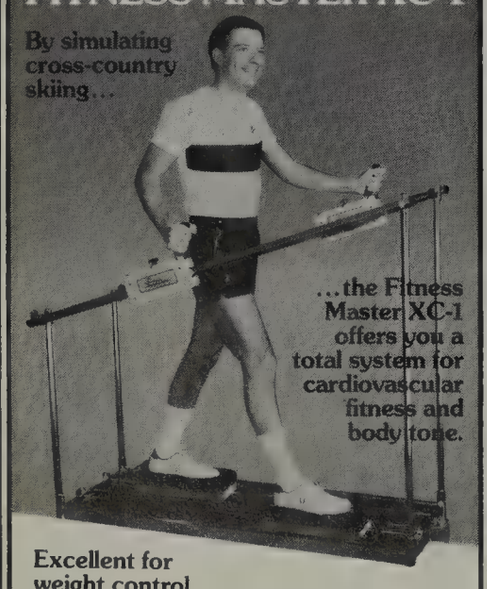
THE
FITNESS MASTER XC-1



By simulating cross-country skiing...
...the Fitness Master XC-1 offers you a total system for cardiovascular fitness and body tone.

Excellent for weight control.

- Fluid motions—no jarring impact on bones and joints. Avoids running related injuries.
- Leg and arm motions are independent, with totally adjustable resistance.
- Can be used by men or women regardless of size or weight. Height adjustable.
- Easily folds to 5 inch height. Slips under a bed.
- 30 day home trial. 2 year warranty.

ering wild resources, but they did so more effectively. The best evidence comes from the coast of southern Africa, where Later Stone Age sites contain abundant bones of flying sea birds and especially of fish, rarely found in earlier sites. The implication is that only Later Stone Age people could systematically obtain fish and fowl. Confirmation comes from fishing or fowling implements, including double-pointed bone splinters, which could have been baited to catch either birds or fish, and stone net sinkers. In general, Later Stone Age people exploited a higher proportion of all available animals, including such dangerous prey as wild pigs. Unlike their predecessors, these hunters had the bow and arrow and perhaps other weapons that allowed attack from a distance.

Two events that occurred at the very end of the Upper Paleolithic, 12,000 to 10,000 years ago, reinforce the idea that these later people differed from their predecessors in their capacity to exploit plant and animal resources. These occurrences were the extinction of a number of large mammal species on various continents and the beginning of plant and animal domestication, most evident in the Near East. Among the species that disappeared in Europe and Asia 12,000 to 10,000 years ago, the most prominent were the woolly mammoth and the woolly rhinoceros. About this time there was a global environmental/climatic change, marking the transition from the last glacial to the present interglacial. One result in Europe and Asia was that the area covered by forest increased at the expense of the open grassland favored by the mammoth and rhinoceros. While this change probably contributed to their extinction, both species had previously survived similar episodes. A reasonable inference is that more effective hunter-gatherers applied the *coup de grâce* to mammoth and rhinoceros populations already much reduced in numbers and distribution.

Similarly, Later Stone Age hunters, in combination with environmental change, probably caused the so-called giant buffalo, giant hartebeest, giant Cape horse, and other species to disappear from sub-Saharan Africa at approximately the same time. As in Europe and Asia, the extinct species had survived comparable environmental change during the Middle Stone Age and earlier times. Finally, people were probably partly responsible for the especially dramatic wave of large mammal extinctions that swept the Americas. The number of species involved was far greater than in the Old World, most likely because people were a relatively new element in American ecosystems.

The causes of plant and animal do tication remain controversial. I believ first steps represent a successful atte by some people to maintain a longstan relationship with animal and plant spe that were becoming rare as a result o matic change. Once again, Middle Pa lithic (and earlier) people experien similar environmental change did adapt in the same way, probably bec of their limited ability to innovate.

In Europe and Asia, as well as Af simultaneous gaps in the occupatio many sites within the same region sug periods of decline in human populati In Africa particularly, there is clear dence that human populations thinne over large areas several times betwee Middle and Later Stone Age and wi the Later Stone Age. The reason probably recurrent hyperaridity. Ne theless, Upper Paleolithic and L Stone Age people apparently were n numerous than earlier people living u similar environmental conditions. In p of Europe, more sites were occupied at any period in the past, and many larger and richer, suggesting that thi flects a genuine increase in human pop tions, not simply greater mobility f site to site. Sites with multiple dwell that may have been simultaneously o pied suggest that group size was la This may have been both a cause an fect of advances in hunting ability southern Africa, human population crease in the Later Stone Age is also cated by the smaller size of limpet s and tortoise bones that accumulate occupation sites, as would result fron creased exploitation of these resourc

Besides increasing their number long-occupied regions, Upper Paleol people also expanded into previously occupied areas, particularly northeast most Europe, northern Asia (Siberia) Americas, and probably Australia. main obstacle to earlier occupatio northeasternmost Europe and nort Asia was almost certainly the harsh and length of the winters, whether du glacial or interglacial periods. Upper leolithic adaptation to these extreme matic circumstances involved well- structed dwellings, tailored clothing, probably also advances in hunting, principal means of obtaining food.

The ruins found at many Upper Pa lithic sites indicate far more substa dwellings than any that can be infe from earlier sites. In addition, some n contain complex hearths designed to hance air flow and, thus, heat produc Tailored clothing is indicated by the ence of well-made bone needles and n

y by skeletons girdled with strings
ds in positions that suggest attach-
to close-fitting clothing. Some Up-
aleolithic sites also contain large
ers of wolf and fox paw bones, pre-
ly the vestiges of skins used for
warmth. There is no evidence that
le Paleolithic people sought or ob-
l fur-bearing animals on such a scale.
occupation of Siberia between
0 and 30,000 years ago was a precon-
of the colonization of the Americas,
cess made possible by a broad land
e that linked Siberia to Alaska dur-
Upper Paleolithic times. The land
e emerged because of the vast
nt of water taken from the sea by the
lacial ice sheets, especially the one
overed Canada from coast to coast.
ugh people may have reached
a at this time, the ice sheet probably
ed their passage south until the start
glaciation, about 14,000 years ago.
e first colonization of the Australian
ent, 30,000 years ago or somewhat
e, is interesting because Australia
hen, as now, separated from the
mainland by open water. During
r Paleolithic times, there may have
less water to cross, but there was al-
some. The first Australians must
fore have had boats, a further indica-
f the innovative ability of even the
st anatomically modern people.
comparison of Middle and Upper Pa-
ic gravesites gives evidence of other
al advances. Middle Paleolithic peo-
when they buried their dead at all,
d them in simple pits containing only
ody. Other items found in these
-almost always animal bones or stone
—may be "grave goods" or, more
, accidental contents of the fill. In
ast, Upper Paleolithic and Later
Age graves often contain art objects
er special artifacts that were deliber-
placed there, perhaps to reflect the
sed's social status or to ease the tran-
to an afterlife.
me Upper Paleolithic sites contain
cts made of stone from distances up
0 miles away or "luxury" materials,
as sea shells and amber, that had
more distant origins. These relatively
goods imply a web of social rela-
ips far wider than any that can be in-
d for earlier people. In sum, in every
tant respect that archeologists could
to observe, the cultures of Upper Pa-
ic and Later Stone Age people rep-
t a quantum advance over the Mid-
aleolithic.
ose who believe that the Upper Pa-
ic evolved locally in Europe, per-
several times, point mainly to sup-
posed similarities between local Middle and Upper Paleolithic artifacts. However, the similarities are far less striking than the differences, and they may be totally coincidental. Everywhere, the changeover appears to be abrupt, with one possible exception: the recent discovery, in France, of a Neanderthal in a very early Upper Paleolithic level. Before the skeletal remains came to light, however, some specialists had questioned whether the kind of artifacts involved were truly Upper (versus Middle) Paleolithic. I have suggested that they reflect contact between Middle and Upper Paleolithic people, before the former were displaced altogether.

The evidence that the Upper Paleolithic and Cro-Magnons intruded into Europe is more compelling. As already mentioned, fossils indicate modern people were already present in the Near East while Neanderthals occupied Europe. Interestingly, the earliest modern humans in the Near East made Middle Paleolithic tools, showing that biological change preceded cultural change. Then, sometime before 40,000 years ago, they began to manufacture Upper Paleolithic stone artifact types and bone points. These appear 40,000 years ago or before in southeastern Europe, but only about 35,000 years ago in western Europe, as we would expect if there had been a movement of Upper Paleolithic people from east to west.

Recently, it has been suggested that modern people appeared even earlier in Africa than in the Near East. Conceivably then, the earliest modern Near Easterners were themselves migrants from Africa. However, the African evidence requires confirmation with fresh, well-dated, more complete human fossils. We also need additional information on the culture of the early Later Stone Age, which appeared during a period when much of Africa was lightly populated because of widespread hyperaridity. Such a climatic crisis may have supplied the selection pressures behind the appearance of both modern people and the Later Stone Age.

Whenever and wherever the Upper Paleolithic or Later Stone Age first appeared, a broad relationship with anatomically modern people is well established. And the extraordinary differentiation in time and space that is a hallmark of the newer cultures and of subsequent history has occurred without any fundamental change in human biology. In contrast, cultural evolution and biological evolution appear to have gone hand in hand in earlier times, and at a painfully slow pace.

Richard E. Klein is a professor of anthropology at the University of Chicago.

"One Son Is No Sons"

Despite increased acceptance of sterilization and a lowered birthrate, India's massive population growth remains unchecked

by Stanley A. Freed and Ruth S. Freed

Devi and her five children were sitting in their village home in north India watching "Star Trek" on television. Caught up in the adventure, the children struggled to understand the English words. Their mother, meanwhile, was explaining why she was not interested in the government's program of birth control. Noting that her first four children had been girls, Devi said, "I would have gotten sterilized if I had had sons instead of daughters in the beginning. My six-year-old son is very weak physically, which is why I want to have one more son. Girls get married and leave the village to live with their husbands; they are no longer your own. A son in the family is necessary."

Already endowed with five children and intending to have at least one more, Devi and her husband contribute to making India a demographic giant second only to China. In 1981, India had 684 million inhabitants, about 15 percent of the globe's population. This figure includes 136 million persons added since the census of 1971, an increment larger than the total population of Brazil, which ranks sixth in the world. The current annual increase of about 15 million is more than double the population of New York City. India's population, now estimated at 735 million, will approach one billion by 2001 and may surpass China's soon after 2025.

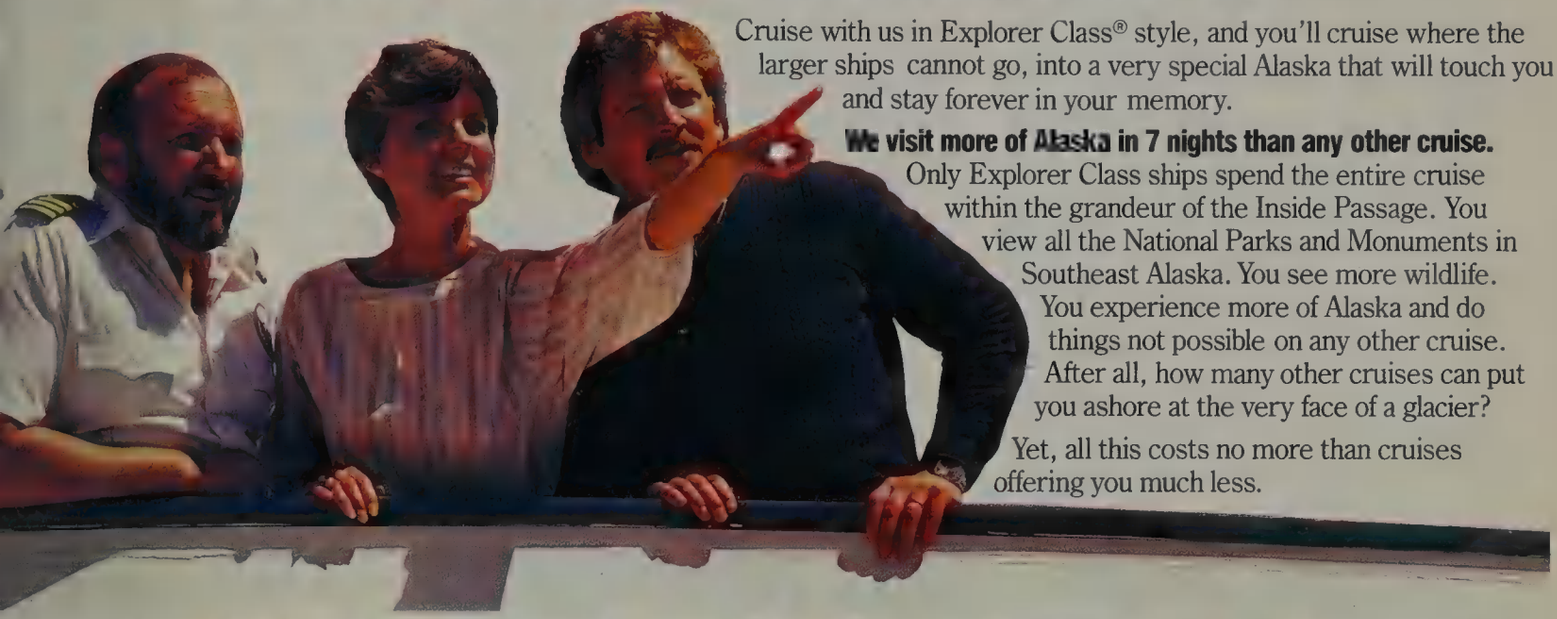
Devi and her husband are not illiterate, poverty-stricken villagers, often thought to be at the heart of India's problem of massive population growth. Devi finished five years of school, and her husband is a high school graduate with a well-paying clerical job in Delhi and a sizable farm in a nearby village. The family is quite prosperous. What impels people like Devi and her husband to continue to have large families in an era of largely free, easily available contraception is that sons are the only dependable insurance against misfortune, poverty, and the disabilities of old age. The vast majority of Indians have no social security, private pension plans, or annuities; they rely instead on their sons. Few couples are satisfied with just one son, for the rate of infant mortality, while steadily declining, is still high enough to make parents with only one son very anxious. "One eye is no eyes, and one son is no sons," runs a popular saying. People try to have two or three sons, hoping that one of them will survive to care for them in their old age.

While a great deal of modernization has taken place in India since independence in 1947, the basic economic arrangements, values, and family roles, which tend to support the desire for a large family, have been generally stable. Even though India's birthrate has dropped and the use of contraception has mounted, India's average annual rate of population growth increased slightly from the 1960s to the 1970s—from 2.20 percent to 2.23 percent—because of lowered mortality. It is this stubbornly high rate of population growth—three times the estimated rate for the United States in 1981—that the government of India is fighting to control. As the late Prime Minister Indira Gandhi was fond of saying, India adds an Australia a year to her population.

In 1951, the year of the first Indian census after independence, the size of the population was of sufficient concern to lead to a national program of family planning, but it was presented in terms of maternal and child health care rather than fertility control. Serious efforts to reduce fertility did not begin until the mid-1960s. The endeavor to check population gro was most intense during the polit Emergency legally proclaimed by Pr Minister Gandhi on June 25, 1975, aft period of political unrest and dema that she resign. During the 21-month riod of the Emergency, which lasted u March 21, 1977, couples were stron urged—by publicity, plus a combina of cash payments and various disincen measures—to undergo sterilization. governmental slogan "Two or three c dren, enough!" was widely dissemina Because the program was often percei as coercive, the ruling Congress Party fered a temporary electoral defeat. spite the popular reaction against the cesses of the Emergency, however, government of India did succeed, m faster than might otherwise have h pened, in establishing sterilization a routine and acceptable option for cou wishing to terminate childbearing.

Today sterilization is the principal c traceptive technique used in India. cause it permanently ends childbear parents do not use it until they have all children they want or think they will ne The present government, concerned v fertility control, extols and publicizes small family of two or three children. dian parents think in terms of two sons one daughter as the ideal "small" fam but in trying for at least two sons they up with an average of about 4.2 child In general, the minority of Indian par who choose to be sterilized do so about children too late from the governme point of view, and the large majority s sterilization altogether, wanting to be v sure that they will never be left withou least one son. "To be sterilized is to ten fate" summarizes a common attitude

CRUISE THE ALASKA THE BIG SHIPS CAN'T.



Cruise with us in Explorer Class® style, and you'll cruise where the larger ships cannot go, into a very special Alaska that will touch you and stay forever in your memory.

We visit more of Alaska in 7 nights than any other cruise. Only Explorer Class ships spend the entire cruise within the grandeur of the Inside Passage. You view all the National Parks and Monuments in Southeast Alaska. You see more wildlife. You experience more of Alaska and do things not possible on any other cruise. After all, how many other cruises can put you ashore at the very face of a glacier?

Yet, all this costs no more than cruises offering you much less.

RER CLASS STYLE
ought a new dimen-
cruising Alaska's
Passage. We take
discover Alaska per-
, at a relaxed and
ly pace. Our ships,
se they're smaller,
ou right into the
of Alaska. There are
wds. There's no wait-
go ashore, like other
s. You'll blend right
y experience Alaska,
eet the people of the
Land.

ONLY EXPLORER CLASS gives you a complete, indepth Inside Passage experience. Special shore excursions are included. We carefully plan for daylight exploring. We visit more ports and scenic areas. You'll see more wildlife, whales and glaciers. We truly feature Alaska!

EXPLORER CLASS STYLE IS INFORMAL GOOD TIMES. You'll be spoiled by a crew whose attentiveness and enthusiasm go beyond service. But most of all, because the ships are smaller, you'll make good friends on board. Friends to share Alaska with, the greatest adventure of all!

EXPLORER CLASS CRUISETOURS. The classic Alaska vacation—an Explorer Class cruise combined with expanded North Country touring. The Best of Alaska touring—the Yukon, Interior, Mt. McKinley, the Arctic—*and* the indepth cruising experience of Explorer Class! No other cruisetour gives you all the experiences and wonder of the Great Land.

EXPLORER CLASS SHIPS are small enough to cruise in close, explore, and easily put you ashore, so you experience Alaska close-up—not at a distance as you would aboard the big cruise ships. Yet, Explorer Class gives you all the comfort you want. Spacious staterooms with air conditioning. Comfortable cocktail lounge, view dining room and expansive decks.

M/S NORTH STAR—NEWEST EXPLORER CLASS SHIP. This Summer you're invited to cruise the Inaugural Alaska Season of the *m/s North Star*, the first totally luxurious cruise ship that's also small enough to be Explorer Class. All the comforts: swimming pool, cozy bars, fine cuisine, theatre, library, lounges, view dining room, generous decks for strolling and large, handsome staterooms.

PLAN NOW for your Explorer Class cruise to Alaska. For reservations or a free brochure, see any Travel Agent, mail coupon or call toll free **1-800-426-0600** (in Seattle 624-8551).

Yes, please send me your new **Cruising Alaska in Explorer Class Style** brochure immediately!

EXPLORATION®
HOLIDAYS AND CRUISES

1500 Metropolitan Park Bldg.
Dept. CLL,
Seattle, WA 98101

The government would like to achieve a family norm of two children by the turn of the century, at which point India's population would begin to stabilize, reaching a plateau of 1.2 billion by the middle of the twenty-first century. Is this goal realistic? The answer must be sought chiefly in India's villages, where 76 percent of the population lives. At various times during the 25-year period from 1958 to 1983, we have had the opportunity to investigate population growth in a north Indian village we call Shanti Nagar (the name is fictitious). The study is of particular interest because it encompasses the demographic watershed between the time that family planning barely existed and the period when fertility control became a serious governmental concern and sterilization was established as the major contraceptive technique. Although one should be cautious about drawing conclusions from a single village, the study of a small community such as Shanti Nagar provides an appreciation of the motives and attitudes that underlie people's everyday decisions about childbearing, family size, and sterilization.

Shanti Nagar is typical of the region that includes the northern states of Punjab, Haryana, western Uttar Pradesh, and the Union Territory of Delhi. From the 1950s to the 1980s, Shanti Nagar has undergone an economic revolution. The village has acquired electricity, brick houses have replaced mud houses, and streets have been paved. In agriculture, bullock power and hand labor have largely given way to machinery. Paved roads and increased bus service make it easier to commute to urban areas, where many men have jobs. Radios are now commonplace, there are some TV sets, and newspapers are delivered daily. The educational level has risen dramatically for both men and women. The village has become more prosperous and better informed about government programs.

Although one would expect that the modernization of education, communications, and the economy would significantly alter family life, the village family has generally maintained its traditional form and functions. A single Indian family may include more people than just a couple and their children: often a family is composed of a couple, their married son (or sons), and his wife and children. Sometimes two or more married brothers live as members of the same family, the eldest brother acting as family head. Families are relatively large by American standards, consisting on average of more than seven members. Men are young when they marry, and women are very young, often beginning their married lives shortly after first menstruation. Men continue to live at their parental home after marriage and bring their brides to live with them. Women are expected to begin childbearing as soon as possible, for both the economic and political strength of a family and a woman's own status depend on the number of sons. "Marriage is not for pleasure," say the villagers. "It is the duty of a wife to have children."

Because attitudes in the 1950s were so strongly in favor of having a goodly number of children, we would have given family planning and, particularly, sterilization little chance of making significant headway. Therefore, when we returned to Shanti Nagar in 1978 after an absence of twenty years, we were startled to hear so many people discussing their own sterilizations or those of their neighbors. We eventually found that there were 68 sterilizations involving both males and females, tantamount to 26 percent of the women of childbearing age (15 to 45 years) at the time. By late 1983, there were 93 sterilized individuals.

The annual index for
NATURAL HISTORY, VOLUME 93

Natural History
Central Park West at 79th Street
New York, N.Y. 10024

Sterilization has run an uneven course in Shanti Nagar. It was accepted slowly at first. From 1968 to 1974, 3.4 individuals on the average were sterilized annually. Then came the twenty-one months of the Emergency, which began in 1975, and the average number of persons who underwent sterilization jumped to about 20 per year. After the Emergency, the figure returned almost to the pre-Emergency norm: from 1977 to late 1983, 4.7 persons were sterilized per year. The big jump in sterilizations during the Emergency was due to the strong campaign mounted by the government. Governmental pressure was especially effective with men holding government jobs. Most of the men sterilized during the Emergency were in government service.

When the Emergency ended, there was a noteworthy change in the proportion of men to women undergoing sterilization. Prior to 1977, 53 percent of the operations were performed on men; for the period from 1977 to late 1983, this figure had fallen to 15 percent. The shift is probably related to the introduction of the surgical technique of laparoscopy, which has r female sterilization easier. The go ment also suggested a somewhat h payment to women undergoing ster tion, compared with the incentive to Moreover, villagers may not have bee tirely convinced that vasectomy was proof. If a vasectomy is done improp a pregnancy can follow, exposing the fortunate woman to suspicion of adul and to village gossip and scorn. Why that chance when a tubectomy will a the problem?

Most of those in Shanti Nagar who cussed reasons for not being sterilize for postponing the operation cited a sufficient number of sons. On the o hand, the expense of raising children overwhelmingly the main reason tha lagers gave for undergoing steriliza Couples also frequently cited the gov mental sterilization campaign, princi its coercive aspects, as a motive for b sterilized, and a few people menti that sterilization was seen as the solu to specific health problems of wome

The emphasis on economic reason cuses attention on the changing valu child labor. In rural India, where chil participate on the family farm fron early age, the value of their labor rem considerable. However, the moder tion of agriculture has reduced the for child labor. At the same time, t has been an increase in employ opportunities that require an educati qualification. Many parents aspire to ter jobs for their children and p fewer, more educated children to mor merous, uneducated offspring. Few afford to educate all the children that can possibly have.

The findings from Shanti Nagar gest that a significant drop in the gr rate of the population cannot be expe in the near term. The parents in Sh Nagar who chose sterilization did so erally after having four or five living dren, and it must be borne in mind most couples have not been steril Overall, completed families in the 1 were larger than those of the 1950s eraging 5.2 versus 5.0 living child Even the women who were sterilize whose husbands were sterilized) in had almost as many living children (a erage of 4.9) as had the women with pleted families in 1958, almost al whom used no contraception.

On the other hand, persons who a pate at least a slight downturn in the of population growth can find grounds for optimism in the statistics Shanti Nagar. In 1978, sterilized mot had fewer living children than

It was a time when cars had tail fins . . .

The Sinister and the Trivial

"We meet the world in many styles, all worthy of attention"

by Stephen Jay Gould

When the old curator of entomology died many years ago, his successor went through his rooms and cabinets, cleaning and sorting to start the new regime afresh (improbable as this anecdote will seem, I know two people who swear that it is true and that they were there). He opened one drawer and found a box designated "pieces of string for future use." Next to it, chock-full of items so identified, lay another container labeled "pieces of string not worth saving."

We note, in this tale, the stereotype of the professional taxonomist—calm, unpretentious, orderly to a fault, and unrelentingly dull. His task, the allocation of nature's diversity into appropriate pigeonholes and the composition of descriptive catalogs to order and access the inhabitants of the holes. Yet the debates of taxonomists are among the most spirited and acrimonious in science. I can't print (even in this liberal journal) half of what I heard in the great wars recently mounted against traditional systematics—first, by numerical taxonomy; more recently, by cladism. These vitriolic debates may only reflect an inverse relationship between importance and intensity—the essence of our concept of pettiness. Yet I prefer to think that they accurately reflect the vitality and excitement of a gutsy profession saddled with an image both unfair and untrue.

This essay describes two tiny taxonomic debates, separated by a century, seemingly unrelated and apparently unimportant in two senses. First, they treat biological variation at the lowest level of differences within a species. Second, they have been expunged from the record of memory for all but a very few specialists—"forgotten even by God," as Browning wrote. They also embody two concepts despised and rejected by decent folks (but providing a handle for my title). First, *aberrancy* as recorded in reversed, or left-handed, coiling of some peculiar snails. These oddballs are technically called sinistral, as opposed to ordinary right-handed, or dextral, snails. The predominance of right-handedness in another species is, of course, the chauvinistic source of our words *sinister* and *dexterous*. Second, *insignificance* as reflected in a debate about how taxonomists should name biological variation at its lowest recognized level of subspecies. (The etymology is, again, curiously appropriate. The second part of a species' designation—the *sapiens* in *Homo sapiens*, for example—is called, technically, its trivial name. The debate about subspecies rested upon a proposal that geographic races be recognized by adding another trivial term to make the full name a trinomial—for example, *Homo sapiens sapiens* for modern humans and *Homo sapiens neanderthalensis* for a famous extinct race. *Trivial* has its vernacular meaning of "irrelevance" and its technical sense, which spurred the debate about subspecies described later in this essay. Its etymology refers to the town gathering spot where three roads meet, hence commonplace. Three roads in the etymology; three names in the taxonomic debate.)

Both small tales also embody, I think, an important lesson about the impact of evolutionary theory and the nature of scientific discovery.

Although Aristotle had denied the possible existence of southpaws among snails, occasional lefties in dextral species had long been prized as curiosities. (A snail shell is a tube closed at its top, or apex, and open at its bottom, or aperture. The tube winds around and down an axis of coi
By convention, a dextral snail opens it

HOW TO HELP A LITTLE GIRL MAKE IT ALL THE WAY TO 7.

It wasn't long ago that if little Kamala
ama drank the water in her village she
ould have taken her life in her hands.
Today, thanks to Save the Children, she
n have clean water to wash with, and
esh water for her mother to cook with.
And she can do something else that
as once unheard of in her village for
ittle girl.
She can go to school. Even go past
e fifth grade.
When you first sponsor a child
rough Save the Children, you have no
ea how much just $16 a month can do.
By combining your funds with
her sponsors', we're helping families,
en entire communities, do so much.
ne result is that children are now get-
ng things they didn't always have:
Better food. Clean drinking water.
ecent housing. Medical care. A chance
go to school.
In fact, for over 50 years, Save the
ildren has been working little life-
ving miracles here in America and
ound the world.
And the wonderful feeling of spon-
oring a child comes to only 52¢ a day.
ne cost of a cup of coffee.
What's more, you'll get a photo of
e child you sponsor, a personal his-
ry, progress reports and a chance to
rrespond, if you'd like.
Please, won't you help. Send in the
upon today.
There are still so many children who
eed the chance Kamala Rama got.
The chance to make it to 7.

Gary Shaye

Because 50 years of experience has taught us that direct handouts are the least effective way of helping children, your sponsorship contributions are not distributed in this way. Instead, they are used to help children in the most effective way possible–by helping the entire community with projects and services, such as health care, education, food production and nutrition.

Established 1932. The original child sponsorship agency. Your sponsorship payments and contributions are U.S. income tax deductible. We are indeed proud of our use of funds. Based on last year's audit, an exceptionally large percentage of each dollar spent was used for program services and direct aid to children and their communities. Our annual summary with financial statement is available upon request.

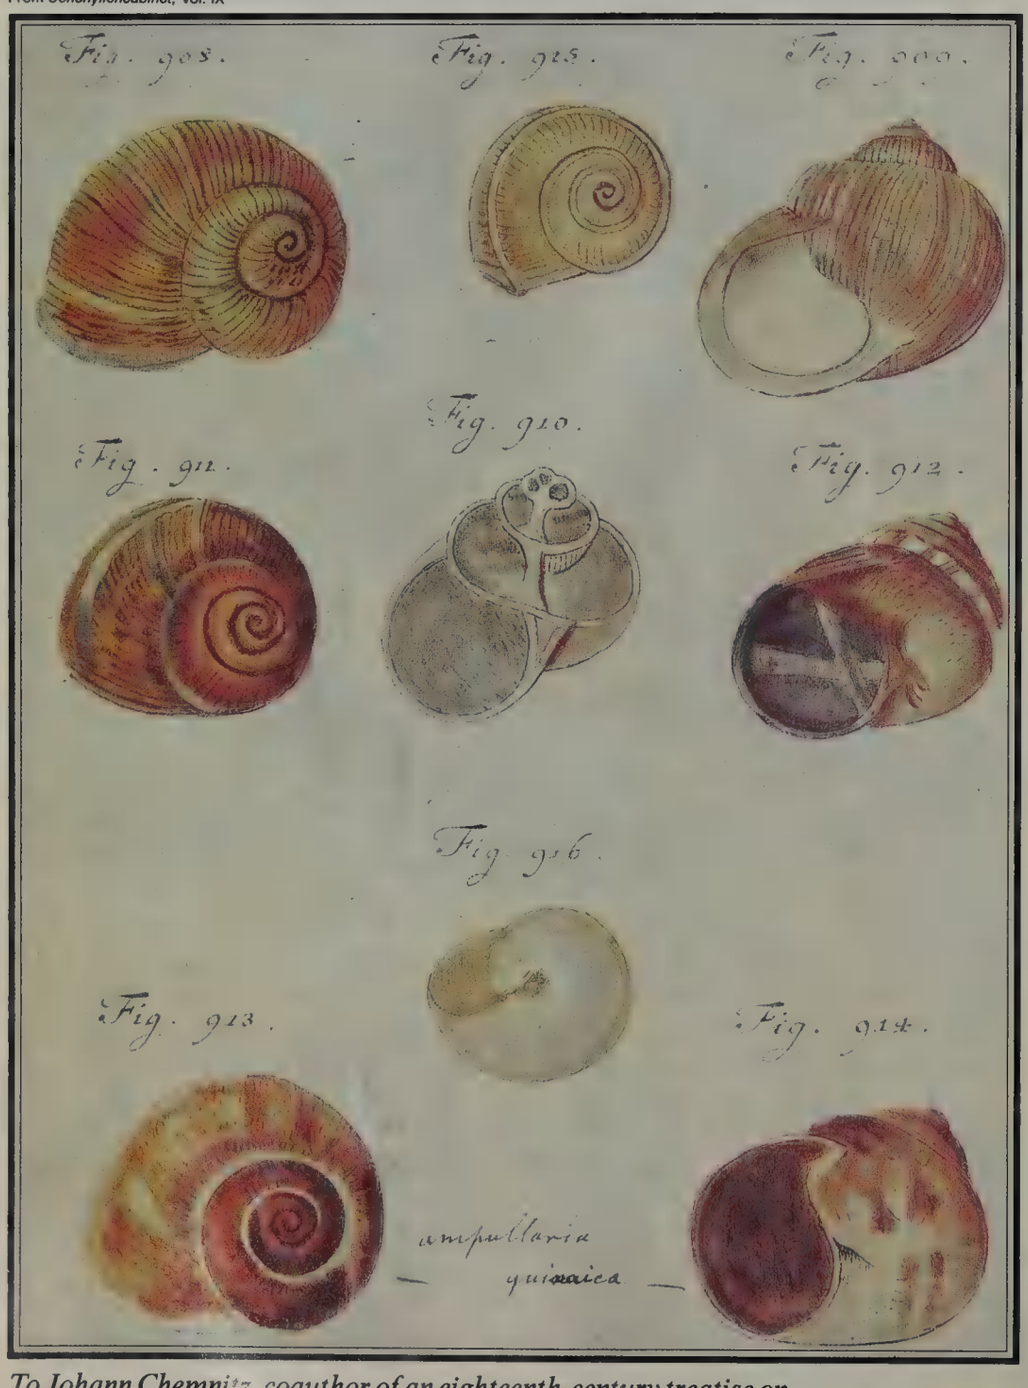
and embryonic museums of Europe. These new creatures were often described in beautiful monographs with exquisite hand-colored plates. Taxonomy was a science in the forefront of thought and aesthetics.

The shells of mollusks are among the loveliest of natural objects. One work stands out for beauty and inclusiveness among eighteenth-century treatises on mollusks—the many-volumed *Conchyliencabinet* (shell collection) of Martini and Chemnitz, two dedicated amateurs who combined careers as physician and preacher with a passionate avocation for shells. Most volumes are compendia of descriptions, species by species, group by conventional group. But volume nine, written by Chemnitz, is organized by concept to discuss a puzzle. It bears one of those glorious old titles that tells you more than you want to know about the contents—*Linksschnecken oder von den verkehrtgewundenen Conchylien, welche gegen die Gewohnheit aller übrigen ihre Mundöffnungen nicht auf der rechten, sondern auf der linken Seite haben, Mit 14 nach der Natur gemahlten und durch lebendige Farben erleuchteten Kupfertafeln* (Left-handed Snails, or inversely wound Shells, which contrary to the Custom of all others, have their Apertures not on the right, but on the left Side, With 14 Copper Plates drawn from Nature and illuminated with natural Colors).

(May I succumb to temptation and float a gratuitous and tangential comment that, I hope, will be read in the intended spirit and not merely as an exercise in vanity and egotism—though I freely confess to both sins. Chemnitz's *Linksschnecken* is one of the most gorgeous books that I have ever had the pleasure to read. T plates are stunning, the typography e gant, the paper thick, textured, a unyellowed by age. But the text is in G man [in the old Gothic script] with lo quotations in Latin. It is therefore clos to nearly all American readers, given c lamentable training in languages. I lo languages and have spent a great deal time learning several. Many colleagu may view this passion as an arcane intere of no particular use in science, a bit of l eral learning to be indulged for perso idiosyncrasy. The personal reasons a sufficient and knowledge need never justified by utility. But I can read Che nitz and they can't, and the ten hours spent with him last week was the best tir I've had in months. All knowledge is us ful. It always "comes round again" li the tune on Arlo Guthrie's guitar. A you never know when.)

From *Conchyliencabinet*, Vol. IX



To Johann Chemnitz, coauthor of an eighteenth-century treatise on mollusks, these leftward-coiling escargots were "errors of nature."

Johann Hieronymus Chemnitz h been forgotten. His name does not ev appear in the sixteen-volume historia bible, the *Dictionary of Scientific Biogr phy*. His treatise on *Linksschnecken* even more obscure, unknown to most pr fessionals. Yet it contains the descripti of an interesting and revealing experime among its pretty pictures and descri tions.

Chemnitz's *Linksschnecken* is writt in a relaxed, almost garrulous style nc unknown in our age of spare and uni spired scientific prose. He begins with effusive dedication to Crown Prince Fre erick of Prussia. Although I suspect th Fred had other fish to fry and little time bother with left-coiling snails, Chemni laid both his volume and specimens "mc respectfully at the feet" of his sovereig He explains that he spent twenty yea scouring all corners and boundari (*Ecken und Enden* in the more euphor ous German original) of the conchologic world, slowly assembling by "costly cc respondence" Europe's finest collection *Linksschnecken*. "And therefore," wrote, "I hope with this volume to provi a welcome gift to all warm friends shells" (who, no doubt, cared a good de more than the crown prince). He then lis and praises the many amateurs and afici nados who helped him *mit Rat und T* (neither gunfire nor rodents, but "advi and action").

Chemnitz decided to concentrate on th subject closest at hand—the occasion lefties found among large and convenie samples of the edible escargot *Hel pomatia*. In his time, these peculiar shel long prized by collectors (who, I trust, a their cake before having the wrappin posed a problem to the prevailing vie

We'll tell you what other Alaskan cruises sweep under the Ugrug.

The folklore of Alaska. The native art. The cultural past. The geologic present. What some cruises don't tell you about Alaska could fill a ship. Our S.S. Universe.

We'll take you to more ports, more shore excursions, uncover more of Alaska than any other cruise line. A two-week learning adventure, guided by our anthropologists, oceanographers and other onboard PhD's.

On a ship of comfortable accommodations, relaxing informality. American and Chinese cuisine. Evenings of classical music. Conservatory ensembles. Dancing to the ship's orchestra.

Starting at only $1595 (per person, double occupancy), 14 days for the price of many 7-day Alaskan cruises. And departures from Vancouver every two weeks, June through August.

What's an Ugrug? Don't bother asking the other cruises. Send for our free brochure today. See your travel agent.

Or call us at (800) 854-3835. In California call (800) 222-2255. Then book your adventure in learning.

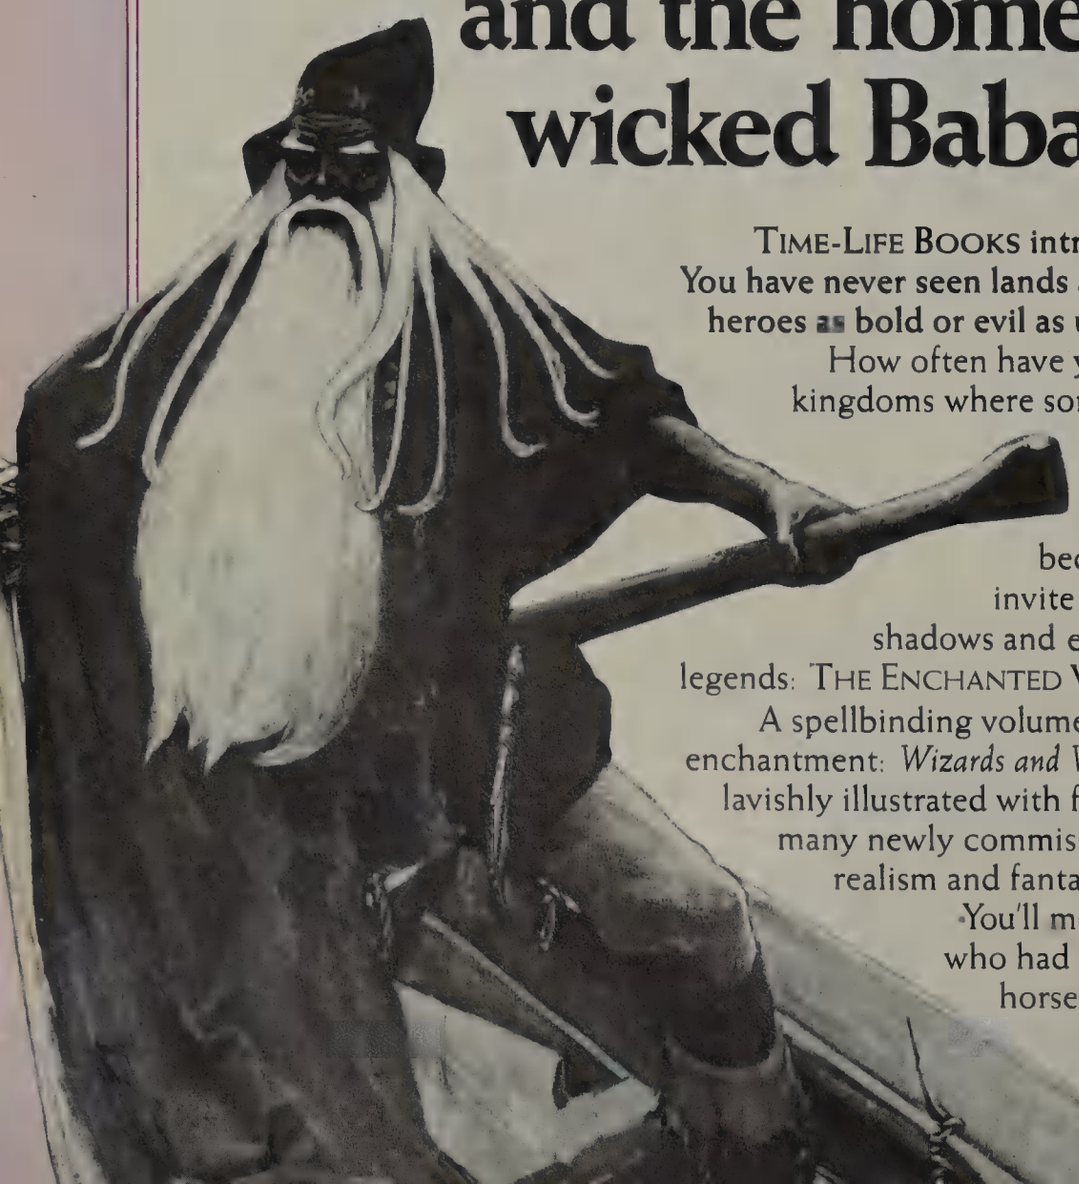
You've been to Oz, Camelot and Middle Earth. Now, wend your way to Kaleva...the land of Taliesin... and the home of wicked Baba Yaga.



TIME-LIFE BOOKS introduces THE ENCHANTED WORLD. **You have never seen lands as fabulous, creatures as amazing, heroes as bold or evil as unspeakable.**

How often have you wondered about the legends of kingdoms where sorcerers prevail? Where elves, gnom and sprites ply their magical powe And unicorns graze in forest glad Now, you can stop wonderi because the Editors of TIME-LIFE BOO invite you to enter this world of sylphs a shadows and explore the realms behind the ancie legends: THE ENCHANTED WORLD.

A spellbinding volume will introduce you to these lands enchantment: *Wizards and Witches*—a sumptuously beautiful bo lavishly illustrated with full-color paintings and drawings, many newly commissioned from today's master artists o realism and fantasy.

You'll meet the legendary wizard Gwydion, who had the power to turn toadstools into horses and forests into entire armies.

You'll be entranced by the story

a Yaga, breeder of violent storms, who fenced her garden with human bones.
Your reading will abound with tales of talismans, charms, runes and riddles. . .
ls, pentacles and other powers of wizards and witches.
You'll become wise in the ways of Merlin, gilder of the glory that was
nelot, and even face the Devil himself with Faustus and glimpse the eerie
elry and rituals of a witches' Sabbat.
We invite you to examine and enjoy *Wizards and Witches* FREE for
days. Keep it by paying just $14.95 ($17.95 in Canada) plus shipping
handling. Afterwards, you can unlock more of the secrets
E ENCHANTED WORLD holds for you in such volumes as
ies and Elves...Dwarfs...Fabled Kingdoms...Dragons...
nts and Ogres.

of species and the stability of nature.

Three years before the fall of the Bastille, and more than seventy before Darwin, species were regarded as stable entities, related not by evolution and descent but as incarnated ideas of God's mind and, therefore, as expressions of cosmic order and harmony. If each species represents a single divine idea, then it possesses an ideal form, or type. The organisms of a species vary, but their differences are accidental or imperfect departures from the abstract essence—an expression of the sad fact that tangible physical objects can never be perfect representations of ideal prototypes. (This approach to variation—viewing differences among individuals as degraded departures from an ideal form—is called "essentialism" since the ideal and unattainable type is the essence of a species.)

Darwin's revolution is often depicted as a substitution of change for immutable stability. But it accomplished so much more. It also turned the study of variation absolutely topsy-turvy—and variation among organisms is (to use that awful neologism) the "data base" of systematics. To Darwinian evolutionists, variation is intrinsic and irreducible—the "real stuff" of nature. Variation among individuals within a species is also the raw material of future evolutionary change. To essentialists, variation is troubling and irrelevant; the more organisms vary, the more the ideal form will be hidden and obscured. What essentialists tried to eliminate as an accidental overlay, evolutionists cherish as essential.

We cannot understand why *Linksschnecken* were so troubling to Chemnitz unless we grasp this fundamental difference. We look at sinistral oddballs today and our fascination is unambiguous—for we experience the gut appeal of their peculiarity, while we regard their differences from ordinary dextrals as entirely friendly and informative, as part of the variation that defines nature and drives evolution. Chemnitz experienced the gut fascination, but everything else about a sinistral snail could only threaten an essentialist. A bit shorter or taller, a bit darker or lighter can be viewed as minor departures of little importance, but reversed coiling seriously blurs an essence. Thus, Chemnitz did not devote a volume to *Linksschnecken* only because oddballs are intriguing; they represented a threat to his world view.

Chemnitz developed a preferred, a priori solution that he proceeded to test. Perhaps the rare sinistral *Helix pomatia*—they occurred at frequencies of one in several thousand in European markets—were not intolerable departures from essence of escargot. Perhaps they really members of a rare and separate cies (not a hopelessly ad hoc prop since Chemnitz had documented sev exclusively sinistral species in his wi wide survey of *Linksschnecken*). If s tral escargots were a separate spe then they would produce left-han progeny when mated. Chemnitz there scoured the food markets of Europe, g ered several small groups of live sini escargots, proceeded to breed them, anxiously awaited the results (and mean "with anxiety," not "eagerly").

Several attempts failed as his sinis fell victim to heat, drought, predatio possible mixture with errant righties nally, he succeeded as his sinistrals m and laid eggs. But expectation, in case, only bred disappointment, for hi bies hatched as a veritable army of Jo Maggios and Tom Seavers. Righties not a lefty among them. He wrote: "T from pure sinistral snails, and agains my wishes and all my presupposit pure dextral snails descended."

Chemnitz used the documents of profession to rue his results, citing in ness Psalm 58:8—"Like a snail w melteth, let every one of them pass a . . . " But he could not deny the conclu and it troubled his essentialist convict deeply: "They are not a new spe . . . They are errors of nature . . . dege ated from their species, afflicted chil of rightborn, rightturned, rightwound ents and grandparents."

Chemnitz's work is from another a so many ways, and its very archa might teach us the potential transi and contingency of our own cherished victions. Chemnitz's essentialism m its difference in substance, but the v tion in style is even more striking. Mo mythology about the "scientific meth requires that we keep desire and expe tion out of our experiments; we are posed to test like objective automata to derive our ideas and theories dire from data obtained with an open and c blank mind. But how can passionate opinionated human beings so behave why should they? What we do requir basic intellectual honesty and respec nature, is rigorous fairness in proce and continuous challenge to prefer and expectation. But how can we sc nize our prejudices if we don't examir acknowledge them? We serve the cau objectivity better by recognizing our subjectivity and guarding against it, by pretending that it doesn't exist.

Chemnitz, unconstrained both by r ern myths and the economics of pub

THE NATIONAL COMMEMORATIVE MINT'S

SOLID GOLD PRESIDENTIAL INAUGURAL MEDAL

LIMITED EDITION

(Enlarged to Show Detail)

100% SOLID GOLD–$20

n January 20, 1985 Ronald W. Reagan, the 40th President of the nited States will officially start his new term. To honor this momen- us occasion, The National Commemorative Mint, Washington, D.C. issuing its Presidential Inaugural Medal in 100% SOLID GOLD. his is the first time a public offering has ever been made of a PURE OLID GOLD medal to honor the Inauguration of a re-elected resident.

100% PURE SOLID GOLD*

ach medal will be individually minted from hand engraved dies cap- ring all of the fine detail of President Reagan's portrait in exquisite ree-dimensional relief. This finely minted PURE SOLID GOLD ece is available exclusively from an office of one of America's private ints, The National Commemorative Mint, Washington, D.C. Each augural Medal is guaranteed and certified to be 100% SOLID OLD—the highest quality gold, and each will be marked with its lid purity of 24KT.—there is no gold purer than 24KT.*

EXCLUSIVE LIMITED EDITION

his is the only time these medals will be made available directly to the ublic. After midnight January 20, 1985 Inauguration Day, no orders r these 100% SOLID GOLD Inaugural Medals will be accepted and e opportunity to acquire them directly at the original issue price of 0 per medal will be gone forever. Each PURE SOLID GOLD medal, easuring 9mm in diameter, will be presented in a special collector's se for their protection and preservation and each will be accompa- ed by a serially numbered certificate attesting to its Limited Edition atus and its purity of solid gold. Further, each SOLID GOLD medal ill be clearly marked on its reverse side with its gold urity—24KT.*

SATISFACTION GUARANTEED

for any reason you are not completely satisfied with your 100% OLID GOLD Inaugural Medal, you may return it within thirty (30) ys of receipt for a full refund. There is a strict limit of five SOLID OLD Inaugural Medals per order. However, you are reminded to act omptly to take advantage of the original issue price of only $20 each orders will not be accepted if mailed after January 20, 1985.

*** 24KT** = 100% PURE GOLD
22KT = 91.67% gold — 8.33% other metals
14KT = 58.33% gold — 41.67% other metals
10KT = 41.67% gold — 58.33% other metals

Wear Your Inaugural Medal Proudly in a Solid 14KT. Gold Frame

ORDERS MUST BE MAILED BY JANUARY 20, 1985

By acting before January 20, 1985 you can assure yourself of acquiring this exclusive, Limited Edition 100% SOLID GOLD Inaugural Medal at the original issue price from The National Commemorative Mint. Never before has a re-elected president of the United States been so honored. These Inaugural Medals in 100% PURE SOLID GOLD, will become true family heirlooms to present to your children and grandchildren as a momentous and valuable remembrance of the second Inauguration of Ronald W. Reagan, our 40th President. However, you are urged to act now while the opportunity is before you, as all orders must be mailed by midnight January 20, 1985 to be accepted. Orders mailed at a later date will be refused and returned. Don't be disappointed—be sure to send your order before midnight January 20, 1985.

For faster service credit card charge orders may call FREE 9 AM—10 PM

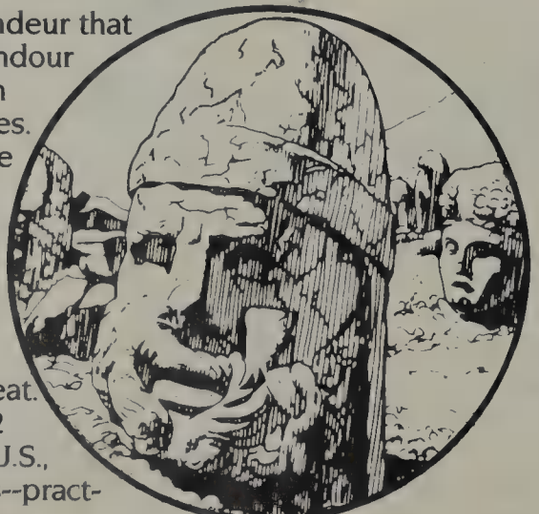
SEE THE WORLD THROUGH AN EDUCATED EYE

Cruise the Mediterranean with Swan Hellenic Cruises in 1985

The glory that was Greece. The grandeur that was the Ottoman Empire. The splendour that was Egypt. It can all be yours in 1985 on one of our 22 exciting cruises.

Only Swan Hellenic combines the delights and comforts of traditional cruising on the yacht-like m.t.s. "Orpheus", with a unique series of informal lectures. No less than 5 experts on the areas visited help you explore the ancient world of Agamemnon and Alexander the Great.



Our 17-day odysseys include 2 nights stay in London, air from the U.S., all gratuities, most shore excursions--practically everything.

Our departures are bi-monthly starting on Feb. 28, 1985 through Jan. 3, 1986. All inclusive rates start at $2,362 including airfare.

For further information see your Travel Agent or write for our 4-color brochure on Swan Hellenic Cruises. And come with us on a memorable voyage of discovery.

naeus's original system was bino-
Each species has but a single name
ɔsed of two parts: its generic name
o in our case) and its trivial name
ns, meaning "wise"—no rule of no-
lature decrees that the etymology be
priate). The binomial system pro-
vides no formal mechanism for naming geographic variation within a species; all humans are simply *Homo sapiens*.

Trinomialism, first advocated as a formal system by American ornithologists in the 1880s, recognized geographic races by adding a third term to the traditional binomial name. At first, most traditional taxonomists hated the trinomial system with all their heart. They had spent a lifetime learning binomial names and mastering a satisfying system for nature's plan. Now some upstarts wanted to go through everything all again, adding third names to parse well-defined species into a plethora of subcategories. Chaos would reign in the profession most committed to order.

But the debate involved far more than convenience, thus defining its interest for us. For the bitter arguments about trinomials record one more skirmish in the continuing retreat of essentialism. Evolutionary theory had forced geographic variation out from under the essentialist rug. Pre-Darwinians had felt no strong need to name geographic races because they only embodied the irrelevant or threatening variation that diluted essences and made

Discover the cool, green, spicy, sparkling, unexpected...

When you emerge from exploring our treasure-filled past, a refreshing new Egypt awaits. Luxurious, air-conditioned hotels. Moonlit cruises down the Nile. Golfing in the shadow of the Pyramids. Invigorating night life. And sensational scuba diving to the depths of the Red Sea. All presented by a country of gracious hosts.

life difficult for scientists committed to defining the ideal forms of God's incarnated ideas. This rationale had been lost by Rothschild's time, but the essentialist desire to view each species as an idealized entity, not as an irreducible cloud of variation, persisted. If trinomialism prevailed, then what was a species anyway? No geographic race could claim primacy of place (or form); all are equal, and a species, therefore, has no essential being, only a set of variations. Chemnitz's experiment (and hundreds like it) forced an acknowledgment of wide variation within species, but perhaps an essence still lay hidden amidst the expanded range. But if species are ordered as series of geographic races, how can any one form be more basic than any other?

Evolution implies the irreducibility of variation at all levels, but views that have comforted us since Plato die hard. Tring's trio began as a small ensemble crying in the wilderness, but trinomialism eventually prevailed, primarily because its underlying philosophy harmonized with evolutionary theory. Ironically perhaps, trinomialism enjoyed only a brief reign and then fell victim to the very movement that had assured its success. We have dropped trinomials again because we have found better ways to express, primarily in graphic and numerical terms, the irreducible geographic variation that defines species and denies them any essential form. Lord Rothschild won his bitter battle, but the names he cherished are slowly fading from use (damned slowly, as indicated by the irate letters this passage will surely elicit from zealous compilers with precious life lists of observed subspecies).

I learned history in school as the story of kings and generals. But armies (and nations) move on their stomachs (snails do too, by the way); no Napoleon can prevail if his quartermaster doesn't deliver the chow. Many academic historians are now trying to recapture the everyday life of peasants, laborers, and shopkeepers, for (perhaps paradoxically) the most dramatic expression of changing contexts must surely be their impact upon routines that regulate our ordinary activity. Yet these activities often become invisible with the passage of time because no one records, in any formal way, what plain folks do all the time.

Our usual approach to the history of ideas suffers from the same myopia of confinement to the movers and shakers of theory. Historians have scrutinized every day of Darwin's life; they have traced in intimate detail the public debates that surrounded biology's greatest revolution. We are assured that Darwin did not arise in a vacuum, that his way had been m straight by social and scientific chan that produced a more receptive world. are also told that his success required sustained effort of innumerable partisa But the foot soldiers of his revolution invisible, their work buried in dusty jo nals on the back shelves of libraries or dustier labels attached to specimens in "storage facilities" of our major museu An army of taxonomists made the croo straight and the rough places plain— they have been forgotten.

I am not saying, in the old positivist dition, that the likes of Chemnitz Rothschild made Darwin by patiently cumulating the facts of nature until t formed a chorus that could not be den Fact and theory form an unbreakable of interaction. One thousand Chemnit establishing ten thousand new facts ab natural variation, paved Darwin's but the grade had been surveyed changes in theory and social cont Chemnitz could ask the right questi and accept the answers that he himself veloped, in part because the late ei teenth century had already become a genial time for theories of dyna change.

But we do obtain a peculiarly skew and discontinuous view of history when view great thinkers as exclusive agent scientific change. Chemnitz and Ro schild pursued their work with the sa dedication, passion, and honest eff they too deserve our respect and at tion—not only for reasons of human s darity, but also in our quest to underst history.

Fractal curves have recently beco popular in mathematics. Such curves oversimplify greatly, maintain their f at all scales. If they are roughly co gated at a grand sweep of miles, they not be smooth over millimeters, but jus bumpy at a properly reduced sc (Coastlines may record a fractal tern—the rocky coast of Maine may be more jagged than the path around s grains along a foot of beach.) Perhaps speak metaphorically, intellectual deba are like fractals—not smooth and u spiring because small in scope, but ful sharp edges and pungency at all sca each piece a model of the whole. In case, as Milton said, we meet the worl many styles, all worthy of attention. So may "post o'er land and ocean with rest," but "they also serve who only st and wait."

Stephen Jay Gould teaches biology, g ogy, and the history of science at Harv University.

How membership works.

1. You receive the **QPB Review** 15 times each year (about every 3½ weeks). Each issue reviews a new **Selection,** plus scores of Alternates.
2. If you want the **Selection** do nothing. It will be shipped to you automatically. If you want one or more Alternate books—or no book at all—indicate your decision on the Reply Form always enclosed and return it by the date specified.
3. **Bonus books for Bonus Points.** For each softcover book or set you take (except for the books in this offer), you earn Bonus Points which entitle you to choose any of our softcover books. You pay only shipping and handling charges.
4. **Return privilege.** If the *QPB Review* is delayed and you receive the **Selection** without having had 10 days to notify us, you may return it for credit at our expense.
5. **Cancellations.** You may cancel membership at any time by notifying QPB. We may cancel your membership if you elect not to buy and pay for at least one book in every six-month period.

Let's try each other for 6 months.

Quality Paperback Book Club®, Middletown, Pa. 17057. Please enroll me in QPB and send the 3 choices I've listed below, billing me only $1 each, plus shipping and handling charges. I understand that I am not required to buy another book. You will send me the *QPB Review* (if my account is in good standing) for six months. If I have not bought and paid for at least one book in every six-month period, you may cancel my membership. A shipping and handling charge is added to each shipment.

WE BUILD OUR STOVES WITHOUT COMPROMISE

Consolidated Dutchwest

ORDER A CONSOLIDATED DUTCHWEST STOVE OR FIREPLACE INSERT BY MAY 22, 1985 & RECEIVE A CORNING CATALYTIC COMBUSTOR FI

n considering a stove or fireplace insert, ifficult to know what features are impor- At Consolidated Dutchwest, our approach our concerns and questions is very ghtforward. We build our stoves without promise. All the important features are -in so they will be there when you need n. We start with safety. Each unit ex- ls all safety requirements. Clean-burning lytic models are available to meet the ected safety and pollution control require- ts of the 1990's now. To very safe ration we add efficiency in an airtight gn with precision controlled combustion. y our stoves, customers consistently report savings of 50%, 70%, even 90% when converted from conventional heating. You expect exceptional savings too.

OOD & COAL URNING CAPABILITIES

afety and efficiency we add wood *and* coal bilities, because fuel flexibility is as in- able as are the coal-related features — if you never burn coal. An ashpan, ash- and shaker grate are essential for burning With wood they are just plain useful — quick fire starting and easy, clean ash oval. Most stoves burn wood *or* coal and ire costly additional parts and time- suming steps to convert from one fuel to other. Our conversion takes *30 seconds.* most popular models provide both radiant convection (circulating) heating. Heat is itarian. It radiates in all directions, in- ing the less productive ones — bottom back. Our convection systems channel air from bottom, back, and top through otrusive vents on the stove front.

AND CAST, RTIGHT CONSTRUCTION

stoves are made entirely from cast iron, cast and assembled from pure, virgin iron. They are airtight to the point that our smallest stoves can hold a fire ugh the night. Our larger units, lit at reak, will still be heating your home well sunset on a single loading of wood. With , the burning times are even longer. All els, including inserts, have polished cook- tops. Most load from front and side. mic glass windows are standard, as is a en for open-hearth burning.

EDERAL PERIOD STYLING

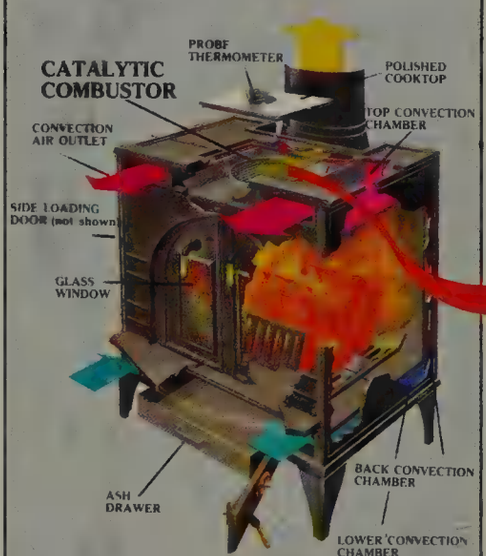
le concentrating on function, we haven't promised on appearance either. We've loyed the simple clear lines of Federal od architecture (1810-1830), as elegant to- as they were then, to create a unique and tiful pattern of raised lines and arches. distinctive pebble finish and solid brass highlight the classic styling. We know our es will frequently be sited in living rooms we've gone to great lengths to assure they ng there. Those of you who eventually a Consolidated Dutchwest stove will find trademark pebble finish is not only tiful, but also increases our stoves' radiant aces by over one-third. Even while stress- appearance we never forget performance.

COMPLETE UNIT

don't believe in options. Too often they k essential features which must be pur- ed to make a stove useable. Our list of op- tions makes quick reading. A Corning Catalytic Combustor to reduce both creosote build-up and pollution *(as much as 90%)* and increase combustion efficiency *(up to 50%)*; a 100 cfm dual-speed fan (standard on inserts) to enhance convection airflow fivefold; a flue adapter to facilitate mounting pipe in tight quarters; a decorative brass rail and mitten rack. All else is standard, including a 30-day money-back guarantee, 3-year warranty and *delivery to your home.*

FREE CATALYTIC COMBUSTOR THIS SPRING, SAVE UP TO $164

To introduce our line of catalytic adaptable stoves, we are giving away a Corning Catalytic Combustor *absolutely free* with each stove purchased this spring. Recently we re-engineered every one of our stoves to be capable of catalytic combustion by the simple addition of a catalytic element. We feel the astounding results achieved by the Corning Combustor, in terms of improved efficiency, cleaner air, and stove safety, warrant everyone having a catalytic stove now. To help make this attainable for everyone, and encourage use of the safest, cleanest burning stoves, we will be including a catalytic combustor *free* with every Consolidated Dutchwest stove purchased by May 22, 1985. And to make it even easier to own a catalytic stove, we will hold over our 1984 prices until May 22, 1985 as well. You can save as much as $164. Write or call today for details.



A Corning Catalytic Combustor can increase stove efficiency as much as 50% while reducing creosote build-up and smoke pollution up to 90%.

Conversion from wood to coal takes 30 seconds.

Standard probe thermometer & polished cooktop.

Front & side doors provide for easy loading of wood.

Slide out ashbin makes emptying easy and clean.

BUILT WITHOUT COMPROMISE SO YOU WON'T HAVE TO.

The Glowing Avalanche

The collections at the American Museum of Natural History contain a number of odds and ends that are probably of greater historical than scientific value. One of the most curious—and, in its way, saddest—collections is buried in the storerooms of the Department of Mineral Sciences. Gathered about the turn of the century by Edmund O. Hovey, the curator of the Museum's mineral collection, it consists of a twisted and partly fused street sign in French, several melted bottles, a melted pewter tankard, and an assortment of "bread-crust" volcanic bombs, ash samples, charred wood, and other bits and pieces.

Hovey gathered these at the site of one of the most devastating volcanic disasters of modern times—the eruption, on May 8, 1902, of Mount Pelée, on the island of Martinique, which resulted in the annihilation of the city of Saint Pierre and the death of its 30,000 inhabitants. When the news of the eruption (and that of the previous day's eruption of Soufrière on the adjacent island of Saint Vincent) reached New York on May 9, Museum president Morris K. Jesup immediately called a meeting of the trustees, and they decided to send the scholarly, bespectacled Hovey to the scene of the disaster to make a firsthand report, take photographs, and gather a collection. Five days later, Hovey boarded the *Dixie*, a United States relief ship carrying food and medicine to the surviving islanders. An expert volcanologist, Hovey knew the dangers of the expedition. Volcanoes almost never erupt once; the initial explosion is almost always followed by even more violent eruptions, mud slides, and earthquakes.

The *Dixie* arrived at Martinique on May 21. A second explosion had rocked the island just the day before, and from aboard ship Hovey could see the vast cloud of steam and ash, punctuated by lightning, hovering over the northern end of the island.

Letters, newspaper stories, and accounts of survivors have given us a vivid picture of the events that preceded the eruption. There had been many signs that the volcano was about to explode.

A year before, a picnic party to the summit of Mount Pelée had discovered a small fumarole, or vent; noxious gases and steam emanating from it had killed the adjacent foliage. A month before the eruption, three loud explosions had rocked Saint Pierre, and the volcano began to smoke. On April 25, two weeks before the disaster, a great black cloud issued from the mountain; in a few days, the fumes and ashes had become so thick that many of the inhabitants of the city could not go outside without covering their faces with wet cloths.

By May 1, the rivers that flowed off the mountain started to rise, and people noticed a number of dead fish being carried along by the current. On May 2, a series of small eruptions dropped a layer of ash on the city. This was followed by a larger eruption and a mud flow that swept down the mountain, carrying huge boulders and uprooting trees. On the evening of May 3, as the volcano belched forth a great cloud of ash, the residents of the city could see great flashes of light and hear almost continuous thunder on the mountain. Birds, apparently felled by poisonous gases, began dropping out of the sky. Quietly, like falling snow, an inch of warm ash blanketed the city.

The first human tragedy occurred on May 5, when a torrential mud slide cascaded off the mountain and swept people to their death before roaring the sea. Minutes afterward, the sea it slowly subsided for a distance of yards, and then just as slowly returned undating the city's sea walls and jet Electricity failed, but it made little dif ence; the city was illuminated by a con ual lightning display, accompanied sheets of flame and thunder from the cano itself. One by one the seven under ter telegraph cables connecting the isl with the outside world went dead. On evening of the seventh, the number eruptions increased, and people be fleeing the city. In a tragically sh sighted effort to stem the panic, French Governor at Fort-de-France clared that the danger would not incre and sent soldiers into the city to prev officials from leaving. To underscore point, both he and his wife went to S Pierre.

At about 7:50 on the morning of eighth, a ship called the *Roraima* was tering the port of Saint Pierre. An e neer was standing on deck, looking at mountain, and he later described the ing eruption. First, he said, a big clou black ash shot out of the top of the cano. Immediately afterward, a sec puff of ash burst from one of the slo This cloud, dense and brownish bla didn't rise as the other had, but settled the slope of the mountain and rus downward toward the city, gathe speed as it went. Surging and rollin great heaving waves, it spread over city. The engineer, seeing the cloud rac toward his ship, took refuge in the eng room, while a friend remaining on d was killed instantly.

top of a nearby rise, said that as the cloud blanketed the city, "there was a blinding flash of fire, and in a moment the whole beautiful city was in flames. The flame seemed to travel like lightning over the city from north to south; but it was not lightning. It looked as if the black cloud from the mountain had been ignited as soon as it reached the city." Within three minutes, the black cloud had incinerated Saint Pierre and killed about 30,000 people. The only survivor was a man named Samson Cil-Barice, who was imprisoned in the Saint Pierre jail at the time. Badly burned, he later described to Hovey how hot sand had spilled through the windows of his cell during the avalanche. The cloud was what volcanologists call *nuée ardente*, or "glowing avalanche," a mixture of incandescent ash, superheated steam, and noxious gases spewed out by certain types of volcanoes. A *nuée ardente* may reach temperatures in the thousands of degrees and will instantly ignite anything it comes in contact with. Cushioned by expanding gas and steam, a *nuée ardente*, once ejected, may race down the side of a volcano at speeds of more than 100 miles an hour. It is probably the most deadly of all volcanic phenomena. The entire city of Saint Pierre literally burned to the ground in a matter of minutes.

On nearby Saint Vincent, Soufrière had erupted the day before, killing 1,500 people and destroying one-third of the island. Most of the people on Saint Vincent were killed by a wall of boiling mud, five stories high, created when the crater's large, blue lake was heaved out by the eruption.

These were the scenes of devastation that Hovey encountered when he arrived at the islands on May 21. He spent his first two days surveying and photographing the ruins of Saint Pierre and talking to some of the witnesses. He especially wanted to make first-hand observations of the topography of the two volcanoes themselves, and his first chance to do this was on Saint Vincent, where the volcano had temporarily abated. He arrived at Saint Vincent on May 23 and on May 31 decided to climb the summit of Soufrière. Accompanied several other geologists, Hovey ascended the hardened mud and ash flows and finally reached the crater rim. From the crater, a huge abyss with a boiling mud pool at the bottom, rose a giant plume of steam and ash. With a thunderous noise tremendous avalanches of rock and ash periodically cascaded down the crater's inner slopes.

The initial explosion, Hovey observed, had knocked down the trees over most of the mountain in a pattern radiating outward from the crater, and their roots had been charred and carved into fantastic shapes "as if they had been subjected to the action of a powerful sand-blast." Hovey collected samples of "bread-crust" bombs (hardened pieces of lava thrown out by the volcano) and took photographs of the desolate scene.

When Hovey returned to Martinique in early June, Pelée was still erupting. Nevertheless, he was determined to climb

At the American Museum

The Last Sailors

The January members' program will explore the vanishing world of seafaring and boatbuilding. Neil Hollander will lecture and show his film, *The Final Days of Working Sail*, narrated by Orson Welles. Hollander spent two years traveling aboard a 32-foot sailboat, meeting sailors from countries as diverse as Brazil, India, and Indonesia. The program is free and open only to members. It will take place on Tuesday, January 15, at 7:30 P.M. in the Auditorium and advance tickets are required. For more information call the Membership Office at (212) 873-1327.

Circles and Starbursts

The January family program for members features *Circles and Starbursts*, a participatory theater experience that demonstrates the hidden workings of planet Earth. Using storytelling, movement, audience participation, and a grab bag filled with treats for children, the program teaches children, ages four to eight, about the atmosphere, rainstorms, the seasons, and more. Three programs will be repeated on Sunday, January 20, at 11:00 A.M., and 1:00 and 3:00 P.M. The program is free and open only to members. Advance tickets are required; please contact the Membership Office at (212) 873-1327 for additional information.

Naturemax Theater

New York's largest indoor screen, the four-story screen of the Museum's spectacular Naturemax Theater, will feature two films in January: the long-running *To Fly!* and the lush *Living Planet*. Members are still entitled to discount tickets for daily showings in the Naturemax Theater. For information about tickets and schedules, call (212) 496-0900.

Planetarium Events

The Violent Universe. Starting January 4 at the Hayden Planetarium, this new Sky Show, narrated by Leonard Nimoy, delves into the mighty forces that shape the universe—black holes, exploding galaxies, even the birth of the cosmos itself. An array of special effects enhances this tour of our dynamic and ever changing universe.

Wonderful Sky. Through dialogue, song, and audience participation, children ages three through six explore the day and night sky, sunsets, rainbows, and distant twinkling stars. Tickets are $3.75 (adults) and $1.50 (children). For information call (212) 873-5714.

Laser Zeppelin and Laser Floyd. Laser visuals and the music of two famous rock groups combine to create a dazzling experience of sight and sound. See *Laser Zeppelin* on Fridays and Saturdays at 7:30 and 10:30 P.M., and *Laser Floyd* on Fridays and Saturdays at 9:00 P.M. Admission for participating, donor, and elected members is $4.00. Tickets can be purchased on the night of the show. For more information, call (212) 724-8700.

Pacific Peoples Celebration

To mark the opening of the *Margaret Mead Hall of Pacific Peoples*, the Museum's Education Department has planned a number of free weekend programs in the People Center. These include Mao dances from New Zealand; dances of Tahiti; traditional beliefs of Polynesia; a display featuring traditional foods and recipes of Polynesia; traditional music of the Philippines; and much more. All programs are free and open to the public and take place from 1:00 to 4:30 P.M. on weekends in January.

Pacific Peoples Film Program

A series of ethnographic films representing cultures of the Pacific islands will be shown on Saturday and Sunday, January 26 and 27, from 2:00 to 4:30 P.M. in the Kaufmann Theater. All films are free and open to the public.

Black Film and the Directive Image

A more positive view of blacks in our society is the theme of an anthology of films to be shown at 7:00 P.M. on three successive Wednesdays, in the Auditorium.

Wednesday, January 16. The Spook Who Sat By the Door. A story of the first black CIA agent, who uses his training to organize a black revolution.

Wednesday, January 23. Save the Children. This film of a concert organized by Rev. Jesse Jackson intercuts montages of black children with performances by such groups as the Temptations and the Jackson Five.

Wednesday, January 30. Ganja and Hess. A tale of a black anthropologist trying to unravel the mysteries of an ancient pre-Egyptian civilization.

ntain, and on June 18 he finally made the crater with a party of geologists various institutions. He later wrote, stood upon the rim of the great active er and looked upon a scene of wild and fying grandeur." Hovey took photohs of the scene and made extensive s for his scientific report.

n June 24, Hovey decided to attempt western side of the mountain, the most gerous route. Since the first eruption, mountain had been shrouded by storm ds and raked by lightning for much of time. On the way up, Hovey and his panions were soaked by torrential s. After making more observations at crater, they began to descend through rge. Suddenly, behind them, the main er began to erupt, enveloping them in and steam and obscuring what little they had. Closer at hand, but invisithe crew could hear a regular series of derous explosions. They had just sed the river flowing through the e when the ground began to tremble a ten-foot wall of black, boiling water ed past, sweeping over the place re they had been moments before. torrent rammed into a bank of ash sliced into its white hot interior, causan explosion of steam that shot hunls of feet into the air. Hovey and the rs barely escaped with their lives, and he wrote, "the whole formed a scene om witnessed, difficult to describe never to be forgotten."

he most terrifying sight of all, though, the city of Saint Pierre itself. Hovey r even attempted to describe what he "The devastation wrought by the tion," he wrote tersely in his scientific rt, "cannot be appreciated from a verdescription." It can be appreciated to e extent, however, from Hovey's phoaphs. They show acres of ruined build- blackened trees twisted into grue shapes, heavy accumulations of on the remains of cobbled streets. One ograph shows the ruins of a distillery re volcanic bombs had punched holes ick iron boilerplate. In another photoh, a cast-iron statue of the Virgin—hing several tons—had been ripped its pedestal and thrown fifty feet.

ovey gathered examples of the damnflicted by Pelée's eruption, and car- them back to the Museum in late Several of the volcanic bombs were layed, but the Museum administraquietly placed the other grim souvein storage. They were brought out for the *Volcano!* exhibition in 1979, will probably not be displayed again many years to come.

Oak Creek Canyon, Arizona

by Robert H. Mohlenbrock

One of the most abrupt geological features in the nation is Mogollon (mŭgēōn′) Rim, a 75-mile-long cliff that separates the cool, moist high country of northern Arizona from the hot, dry deserts to the south. Alternate Highway No. 89 plunges over the 1,000-foot rim and twists down steeply, finally bottoming out along Oak Creek. The highway then continues south, through a corridor of populated private lands surrounded by the wilderness of Coconino National Forest. In a few miles, close to the postcard-pretty town of Sedona, Oak Creek Canyon's red rock formations burst into view. Traffic slows as each turn in the road reveals cliffs, buttes, and occasional arches tinted in pink, purple, and fire-red. Finally, at Bell Rock, a few miles south of Sedona, the red rock country vanishes as suddenly as it appeared.

The canyon walls consist of five layers of rock, each formed by a different geological process. The bottom stratum, the Supai formation, is a series of brilliant red siltstones and shales, up to 1,800 feet thick, laid down by streams on an ancient flood plain. Above this is a 500-foot band of buff-colored Coconino sandstone formed by windblown sands, 200 feet of white Toroweap sandstone deposited by water, and a 300-foot layer of gray Kaibab limestone created from the shells and other remains of sea animals. Black lava from several volcanic flows caps the whole at certain places.

Sometime during the canyon's geological history, these rock strata slipped vertically, creating faults. Normally, when rock bends along a fault, the layers in the uplifted portion bend downward, and the layers that move down bend upward. In

Willis Peterson

Oak Creek Canyon and some of its side canyons, an unusual phenomenon can be seen: the layers of the uplifted rock bend upward and the downward-dropped strata bend down. Geologist Brainerd Mears suggests that Oak Creek Canyon's rocks did not bend when the faults were first formed. Sometime later, he argues, horizontal compression buckled the layers at the faults to create the pattern we now see.

This feature, called reverse drag, is particularly evident along one of Oak Creek Canyon's side canyons, West Fork, whose steep cliffs and gentle benches were cut by water draining from Mogollon Rim. (Zane Gray lived here for a while and was inspired to write his *Call of the Canyon.*) West Fork supports an exceptional diversity of plants and plant communities for such a small area. To preserve the region for study, the U.S. Forest Service has designated a portion of West Fork as a Research Natural Area.

The West Fork stream runs through one of the richest riparian habitats in Arizona. Dense colonies of jointed-stemmed horsetails grow in the shade of box elders, Arizona walnuts, New Mexican alders, bigtooth maples, and Gambel oaks. During the summer, patches of the showy, yellow monkey flower alternate with the horsetails. On my first hike along the West Fork, I encountered a small, much-branched tree whose fruits resembled hops. The tree proved to be Knowlton's hop hornbeam (*Ostrya knowltonii*), one of the rarest woody plants in the southwestern United States. This hornbeam, which was discovered in the Grand Canyon, also grows sparingly in southern Utah and again in the trans-Pecos area of Texas and New Mexico.

The box elder and Knowlton's hop hornbeam provide examples of how geographical distribution, ecological requirements, and external features—including the continuous or discontinuous gradation of characteristics—are important in determining whether a plant is a distinct species. The box elder, a member of the maple family, has one of the broadest geographical ranges of any woody plant in North America. Common in the eastern United States from Vermont to Florida, it is also found throughout the nation's heartland and as far west as central Montana, Nevada, and California. It even penetrates southern Canada and Mexico. Throughout all of its range, the tree displays similar compound leaves and pendulous, winged fruits. While box elders along West Fork have leaflets that are a little thicker and a little hairier than those of box elders back east, in all other aspects the plants are the same, including the stream bank habitat. In addition, box elders from all across the United States show only a gradual transition in thickness and hairiness of the leaflets. For this reason, botanists confidently classify the box elder as a single species.

On the other hand, botanists recognize two species of hop hornbeams in North America. The eastern hop hornbeam (*Ostrya virginiana*) lives from Nova Scotia to Florida, and west to the Dakotas, eastern Texas, and into Mexico. This small tree usually inhabits moist but well-drained slopes and ridges. It has pointed leaves and two-inch-long fruits. Several hundred miles to the west, a second hop hornbeam with rounded leaves and fruits that barely reach one and one-half inches in length grows in isolated rocky canyons. This is Knowlton's hop hornbeam, considered a distinct species because of its geographical isolation from the eastern hop hornbeam and because of the marked variation in its leaves and fruits.

The remarkable biological feature of West Fork is that within just a few hundred feet of the wet, riparian habitat, there are two other, very different environments. Where the canyon runs almost due east–west, the slopes that face southward enjoy relatively dry conditions, and the branched, leather-leaved shrubs have developed into a brushy, dry plant community called chaparral. Many areas of the chaparral are almost impenetrable because of the entangled growth of the pointed-leaved manzanita, mountain ma hogany, silk-tassel bush, and shrubby liv oak. Prickly pear cacti and century plant found in openings in the chaparral, are re minders that the desert is not far away.

A short distance from such warm, dr areas are stands of Douglas fir and por derosa pine, trees normally expected a higher elevations, such as Mogollon Rir itself. These are able to grow where th canyon bottom is densely shaded. Suc cool and moist conditions are especiall evident in West Fork's narrow side can yons, where the steep walls block the sun' rays. The upper ends of these side canyon are natural channels for cool air.

Beneath these conifers is a contrastin mixture of the pink-flowered New Mexic locust and the Gambel oak. The quiet ob server may hear or see an Abert's squirre a golden-mantled ground squirrel, a wes ern tanager, or a pygmy nuthatch as scurries down a tree trunk.

Although Oak Creek and West For canyons can be visited at any season of th year, the traveler must be prepared fo temperature fluctuations. Summer tem peratures average 75 degrees Fahrenhei but occasionally climb to 100. In winte the average temperature is between 3 and 40 degrees, but it can fall below zer on the rim. Afternoon thundershowers ca be expected during July and August, an there may be snow or light, steady rai during the winter.

"This Land" highlights the biologica phenomena that can be explored in th 153 United States national forests. Rob ert H. Mohlenbrock, a professor of bo any at Southern Illinois University a Carbondale, is author of The Field Guid to U.S. National Forests.

Birds of Fire

Is the bald ibis's affinity for burned grasslands an acquired taste? Or is it an ancient product of evolution?

by David E. Manry

The Drakensberg escarpment of southern Africa rises abruptly out of the gently rolling landscape of the Natal midlands. From a distance, it resembles a colossal fortress wall, towering more than 3,000 feet above the fractured sandstone terraces skirting its base and surmounted by a lofty, summit plateau almost two miles above sea level. From the Soutpansberg Mountains in the Transvaal (the northernmost province of South Africa) to Xalanga Peak in the eastern Cape Province, the escarpment winds almost continuously for more than 1,000 miles, creating the twisted mountainous backbone of the southern African subcontinent. From June through August (winter in the Southern Hemisphere), its basaltic crags and precipices are often completely blanketed in snow; on sultry summer afternoons (December through February) dark thunderclouds loom ominously above its jagged crestline before sweeping over the adjacent foothills.

Extending from the escarpment on both sides is a vast expanse of open grass country, referred to by ecologists as the South African grassland biome. Rising gradually from about 900 feet to more than 11,000 feet above sea level, and covering an area of approximately 126,000 square miles, the grassland is a self-contained habitat "island," surrounded at lower elevations by heath, woodland, and semidesert plant communities. Many plant and animal species are unique to this sprawling grassland, which may have originated as recently as sometime during the Pleistocene period. One of the rarest and most peculiar of these is the bald ibis (*Geronticus calvus*), found nowhere else in the world but the wind-swept grasslands flanking the Drakensberg escarpment. I traveled to the province of Natal, South Africa, in May of 1978 to begin a three-year field investigation of this unique bird. In the process I discovered how important events in its annual breeding cycle are timed to exploit the pattern of insect abundance and availability created by grass fires.

The bald ibis is one of thirty-two different species in the avian family Threskiornithidae, found on all continents except Antarctica. Often highly gregarious, ibises forage in flocks during the day and retire to communal roosts in the evening. They are commonly associated with marshes and other aquatic environments where, by probing in soft mud with their long, curlewlike bills or groping in shallow water, they prey on a wide variety of small animals, including worms, mollusks, crustaceans, insects, fishes, and amphibians.

In keeping with their sociable habits, most ibises breed in colonies numbering from a few pairs up to several thousand, although for some species, solitary nesting is the rule (a few species nest both colonially and solitarily). Most ibises place their nests—sturdy, bowl-shaped platforms composed of loosely interwoven sticks and twigs and lined with a thin layer of grass or some other fine material—on a branch in a tall tree or bush, in dense reeds, or even on the ground when nesting on remote islands safe from predators. The bald ibis, however, breeds exclusively on sheer cliffs. Mated pairs construct their nests well out of the reach of most predators—on narrow, exposed ledges, in potholes high up on mountainsides, in river gorges, and at waterfalls. The only other ibis species that breeds exclusively on cliffs is the bald ibis's sole congener, the waldrapp (*G. eremita*) of Morocco and Turkey, an endangered species very simi-

Nearly fifty bald ibis pairs nest on the cliffs beside the Mooi River, below, in Natal Province, South Africa. The local landowners' practice of burning back ungrazed pastureland, left, provides the birds with a windfall diet of roasted insects during winter and spring.

Mandy Hedden

David Manry

lar in habits and appearance to its southern African counterpart.

The bald ibis is confined to rugged, mountainous country in the eastern Republic of South Africa, extending marginally into the adjacent kingdoms of Lesotho and Swaziland. In South Africa the species was formerly found in the Cape Province as far west as the Atlantic coast, but by the turn of the century the bird had vanished from the western portion of its range, perhaps as a result of overhunting and other human disturbances. Today it no longer breeds in the Cape Province. Moreover, recent decades have seen its numbers diminish in some areas where it has managed to survive. The contraction of the bald ibis's range and its diminution in numbers are particularly ominous because the waldrapp, its closest living relative, has suffered an even more drastic attrition in recent years and today ranks among the rarest of birds.

Some conservationists believe that the bald ibis is also in serious jeopardy. Up-to-date information is lacking, but in 1971 its total breeding population was estimated at only 2,000 birds. The species' vulnerability underscores the need for basic information about its feeding ecology, habitat requirements, and reproductive potential.

My study area was located at approximately 4,000 feet above sea level in what was predominantly open grass country, punctuated by scattered, cultivated fields and crisscrossed by plantations of exotic trees. Winters are cold and dry, with temperatures dropping well below freezing almost every night, while the spring and summer months (September–February) are generally warm and rainy. For three consecutive breeding seasons (1978 1980), I lived in a rustic, mud-and-thatc hut near a spectacular, 130-foot-high w terfall on the Mooi River, where approx mately forty-eight pairs of bald ibis nested each year. Throughout my invest gation I kept track of the number of ibis in the colony at different times of the yea and during each breeding season (prima ily June–November) I monitored the r

luctive activities and success rate of
esting pairs.
ne of the primary goals of my re-
ch was to elucidate the bald ibis's
ing ecology by examining its choices
oraging habitat in different seasons.
sampling technique was straightfor-
d and nondisruptive: each time I en-
ntered the birds feeding, I recorded
number of individuals present, the

A yearling bird (foreground) forages with an adult on recently burned grassland. Winter burning of firebreaks is particularly well timed to provide abundant, easily procured protein during the coldest time of the year.

David Manry

type of vegetation they were foraging in, and sundry details such as foliage height, weather conditions, date, and the time of day. As my observations accumulated, I was surprised to discover that the bald ibis, unlike most members of its family, is strictly a terrestrial forager. It feeds exclusively in natural grassland and cultivated fields, where it consumes beetles, grasshoppers, and other small animals. The birds are rather fussy in selecting the areas they forage in, preferring level terrain where the foliage has been either cropped short by grazing ungulates or burned off. Here they move rapidly with little interference from the sparse vegetation, which provides scant cover for fleeing prey. As an additional bonus, recently burned grassland is littered with dead insects fallen victim to the fire, providing a feast for bald ibises and other insectivores. These fire-killed insects are only slightly scorched and no less edible than their living counterparts. Once located, they require no additional pursuit, so the birds spend less time and energy chasing after meals.

Burning occurs annually in the bald ibis's grassland habitat, and the bird's relationship with fire is remarkably complex. Modern landowners burn the grassland in two distinct seasonal phases. During autumn (March–May), as rainfall and ambient temperatures steadily decline, the grasses prepare for their long winter dormancy, withdrawing most of the nutrients in their leaves to their root systems and releasing surplus moisture to the air. As the foliage withers and dries out, the entire grassland becomes highly inflammable, increasing the threat of destructive, runaway fires.

Therefore, as a safety precaution, landowners burn wide strips of grassland across their properties from late May till the end of July, creating a protective network of firebreaks throughout the landscape. This is the first burning phase. During winter bald ibises forage extensively on these firebreaks, feasting on the numerous dead insects present immediately after burning and returning periodically in succeeding weeks to search for live prey that persist in the grassland long after the fires are extinguished. Since firebreaks are burned annually, the birds are assured of a plentiful and predictable supply of easily procured food during the coldest and driest time of year.

With the arrival of the first spring rains, usually in late August, landowners again burn the grassland, this time in vast sections. This second, far more extensive controlled burning eliminates moribund fo-

Pair bonding often extends beyond the breeding period, so that copulation, below, does not always signal readiness for egg laying. Males of adjacent nesting pairs, top right, engage in the bloodless combat of ritualized bill sparring. An incubating adult, far right, turns its eggs, while another sits tight. Both sexes incubate the eggs; the changing of the guard is accompanied by an "ecstatic" greeting gesture, bottom right.

All photographs by David Manry

liage left over from previous growing seasons and promotes fresh growth for livestock. As the season advances, grasses emerge from their winter quiescence and resume active growth, sending up new shoots to the surface and providing optimal forage for grazing ungulates and herbivorous insects alike. In South Africa, national and provincial laws limit the duration of the controlled-burning season from mid-August to the end of October. Throughout this period bald ibises forage extensively in these vast burned areas, preying on the numerous insects attracted to the nutritious, postfire regrowth. However, the extent of grass burning in any given year depends greatly on the amount of rain that falls before and during the prescribed period. In wet years up to 40 percent or more of the total grassland area may be burned, while during a severe drought almost no grass is burned apart from firebreaks. The birds must then seek other foraging habitats, resorting mostly to cultivated pastures and unburned grass that has been heavily grazed.

The bald ibis's annual cycle, and particularly the timing of its breeding activities, tie in closely with the controlled burning rhythm in its grassland domain. Birds that temporarily vacate their colonies during the nonbreeding period return from their wanderings in early winter, soon after the resumption of firebreak burning, to join up with their previous mates or to form new pair bonds and reestablish their ledgetop breeding territories. Whereas from January to early May the birds spend most of the day foraging afield, retiring to the colony in late evening to roost overnight, beginning in late May they return to the colony much earlier in the day, sometimes after only three or four hours of active foraging early in the morning. Such a drastic reduction of the daily foraging period attests to the abundance of food to be found on burned firebreaks during winter. For the remainder of the day, the birds may be found at the breeding colony, guarding their nest sites against intruders and engaging in courtship activities, mating, nest building, preening, loafing, and bathing in the river. Ironically, winter is a time of relative leisure for the bald ibis, when most other grassland inhabitants are struggling for survival. In late July or early August, the females begin to lay clutches of two or three eggs.

In late August, as fresh growth reemerges on the firebreaks, the first ibis hatchlings emerge from their eggshells. Completely helpless at birth, the nestlings spend their first seven weeks or so confined to their natal ledges, where they a cared for by both parents. They are fed gurgitated insects gathered primar from freshly burned grassland, fro older, greening burns, and from cultivat ryegrass pastures, which serve as a back food source when burned grassland is short supply. During the last stages of development, the nestling frequently p forms flight exercises *in situ*, flapping wings energetically while jumping up a down on its ledge, preparing for the d when it makes its first flight. In a fav able year with abundant rains, when sects are abundant and burning wi spread, 45 percent of all breeding tempts produce one or two fledged o spring. During a severe drought, howev little grass is burned and the birds suff on two accounts. Prey is not only mo scarce but also more difficult to catch

unburned grass. In such years most eeding attempts end in failure, and ne pairs refrain from nesting alto- her.

After fledging, the young ibis begins to plore the cliffs around its nest site, min- ng with other fledglings in the colony ile waiting for its parents to return peri- ically with food. The fledging period ex- ds from mid-October to late Decem- , although most chicks are fledged by d-November. Two or three weeks after dging, the young initiate accompanies parents to the feeding grounds for the t time and begins to develop the forag- skills necessary to become self-suffi- nt. The adults continue to provide sup- mental feedings to their offspring for other two months.

By early summer, when most burned ar- s are covered in tall, postfire regrowth, bald ibises shift to feeding in heavily grazed grassland and cultivated pastures, where the foliage is kept comparatively short. Plant growth is rapid and nutritious herbage abounds, and insects are now approaching their annual peak in numbers. However, the height and density of the vegetation force the ibises to search more carefully for their inconspicuous quarry, slowing their progress and reducing the number of successful captures made in each hour of hunting.

Interestingly, most pairs complete their nesting cycle before summer, raising their ledge-bound progeny during spring, when insects are generally less abundant but are more readily available in burned areas. Later on, when the new fledglings are able to commute to the feeding grounds with their parents, the adults can better afford the extra time needed to locate prey in suboptimal habitats; the time previously spent traveling between hunting ground and nest can now be used for capturing insects with the fledglings at their sides. Moreover, early nesting allows the young birds to develop their own hunting skills in the summer, when insects are most numerous. Thus the number of free-flying birds in the colony and the number of insects in the grassland reach a peak together in late December.

The bald ibis is not distributed throughout the grassland biome but is concentrated in the high-rainfall zone along the Drakensberg escarpment and its main outliers, between 3,000 and 7,000 feet above sea level. The first Europeans who began settling this region in the early 1800s designated the highland grasses as "sour," referring not to their flavor but to their low nutritional value to livestock during the winter months. Because sour grasses withdraw most of the nutrients in their foliage to their root systems during autumn, they are relatively unpalatable to grazing ungulates until the renewal of growth in early spring. Before the advent of artificial feed supplements, livestock had to be herded to lower altitudes each autumn, to rangelands dominated by sweet grasses, which remain nutritious year-round. There they could graze throughout the winter, before being rotated to the highlands again in early spring.

Although grassland ecologists have yet to determine why some grasses are sour and others sweet, they do know that sour grasses tend to grow at high elevations, where annual rainfall is high and soils heavily leached and highly acidic. Sweet ones, on the other hand, predominate at lower altitudes, where the climate is drier

A male parent stands guard over two nestlings, below. A full-time guard is necessary to insure survival of young chicks, which are often harassed by unrelated adults. Opposite: River bathing may be particularly important when ash accumulates in a bird's feathers.

David Manry

and the soils less acidic. Intriguingly, the breeding range of the bald ibis follows the distribution of sour grasslands along the major watersheds and does not extend into the sweet grasslands covering the lower basin regions. Could it be that the birds also recognize the distinction between sweet and sour grassland, and if so, why are they so partial to the latter?

Regional differences in burning frequency could be of crucial importance to a pyrophilous species like the bald ibis. Nurtured by abundant annual rains, sour grasses produce tremendous amounts of herbage during each growing season. Ungrazed foliage must be burned off once every two or three years or the grasses begin to die under the burden of their own accumulating litter and are replaced by weeds, shrubs, and tree seedlings. On the other hand, this problem is rarely encountered in the drier sweet grasslands, where livestock more thoroughly graze the less prolific growth. Here excess foliage rarely has a chance to accumulate.

Landowners may burn their sweet pasturage once every ten or fifteen years to eliminate undesirable plants that invade during a prolonged absence of fire or after an exceptionally wet rainy season, when the sudden flush of growth greatly exceeds the grazing capacity of resident livestock. Otherwise, burning is generally discouraged in the sweet grassland and is rarely practiced. That the bald ibis is restricted to the type of grassland subject to the highest frequency of burning under modern farming systems and is absent from those areas where grass fires almost never occur suggest that burning frequency may be an important factor determining the present limits of its restricted range.

Modern grass-burning procedures have developed gradually over the past century, and the bald ibis has accommodated itself to these artificial fire regimes imposed by recent European settlers on its grassland domain to such an extent that it may now depend on frequent grass fires for its viability as a species. But fire is not new to this region, and the bird's relationship with fire is probably an ancient one. Undoubtedly, the Iron Age pastoral communities that migrated to southern Africa from the north approximately 1,800 years ago tended sheep, goats, and cattle and burned grass regularly in a manner similar to the modern practice. Prior to their arrival, the grassland was populated for millennia by nomadic Stone Age communities that subsisted entirely by hunting and gathering. These early inhabitants burned off large areas of grassland both to stimulate flowering in important food plant that conceal their edible portions under ground and to attract game close to their encampments. Stone Age cave painting in the Drakensberg depict the bald ibis i its characteristic foraging posture, sug gesting that it occupied a special place i the folklore of these communities.

No one knows when people first bega burning the vegetation of southern Africa although recent archeological findings i Zambia indicate that central African cu tures were proficient in the use of fire a least as early as 750,000 years ago. Hov ever, a growing body of evidence suggest that fire was a regular event throughou the grassland biome long before people be gan using it there. Today, the single mos important natural cause of fires in vegeta tion is lightning, and the grassland biom experiences the highest frequency of ligh ning in all of southern Africa, averagin more than thirteen ground strikes pe square mile annually. Along the Draken berg escarpment, the abrupt topographi changes provide ideal conditions for th formation of thunderstorms, and the ligh ning frequency increases to forty groun strikes per square mile annually.

Obviously, the potential for lightning ignited fires is extremely high throughou the grassland biome, particularly alon the Drakensberg escarpment. Conse quently, the local flora has evolved t withstand frequent burning. Indeed, witl out occasional fires, the grassland is grad ually invaded by weeds, shrubs, and othe precursors of successionally more ad vanced plant communities and is eventu ally converted into forest, heath, or wood land vegetation. Thus, the grasslan biome may owe its origin to the high fr quency of lightning storms generate along the Drakensberg escarpment, whic ignited fires at sufficiently short interva to prevent shrubs and tree seedlings fro becoming firmly established, and whic promoted the fire-resistant grasses an forbs in their stead. If this scenario is co rect, the bald ibis's predilection for feed ing in burned areas may be the result of long, ongoing process of natural selectio rather than a fairly recent accommoda tion to human burning practices.

The Little Foxes

They may look endearing, but young red foxes fight violently and, when necessary, steal food from one another

by J. David Henry

It happens during the coldest part of the year—a time when northerners bundle up against twilight days and −40 degree air with parka and wind pants, gauntlet and mukluk. It is a time when darkness pervades the forest, when everything seems brittle.

Yet, during this inhospitable period in late January or early February, while most animals are simply trying to survive the frozen wastes of a boreal winter, red foxes begin to court. It is not difficult to know when the foxes are feeling amorous; a musky odor begins to emanate from the urine they leave in the snow. This scent is particularly strong in the urine of males. In Prince Albert National Park in northern Saskatchewan, where I do my research, foxes develop this breeding odor over the course of a week or so. Then, for the next month or six weeks, a skunky fragrance permeates the woods wherever a red fox and his vixen have established their territory, the area they use for hunting and scavenging and defend against other foxes. After studying foxes for years, I can say with confidence that it is my nose, more than anything, that first tells me the foxes are courting.

During this amatory interlude, the dog fox and vixen, both of which have been leading solitary lives on the territory, now begin to seek one another out. They travel together for several weeks, becoming increasingly confident about touching one another, until they finally breed. During the courtship period, the vixen visits and cleans out several lairs on the territory, one of which she will choose as her whelping den.

Why does a vixen choose to give birth to her pups in one place rather than another? What does she see in a particular piece of earth? After surveying thirty-five whelping dens, I found that they have certain typical characteristics. The den is usually located on a hillside in sandy loam. It is often in the forest but close to a meadow or open slope. And it usually has multiple entrances, the largest one about ten inches in

This article was adapted from *Red Fox: The Cat-Like Canine*, by J. David Henry, which will be published this year by Smithsonian Institution Press.

A red fox plunges through a January blizzard in Ontario. At Prince Albert National Park in northern Saskatchewan, red foxes begin to seek out mates in the worst cold of winter, and their urine takes on a musky breeding odor.

Wayne Lankinen; Bruce Coleman Inc.

diameter. Finally, the den retreat is normally within one hundred yards of a water source, although this source can be anything from a large lake to a humble pool in a muskeg. With these requirements, vixens have to be selective about where they bear and raise their cubs.

Certain features, such as the nearby drinking water, have obvious advantages; but I was not sure I understood the others. Why are they so common? After reflecting about them, I feel that vixens probably select sandy loam because they can dig into it more easily, but it could also be that this soil, combined with the hillside location and nearby open area, may make for a site where snow melts early, frost leaves the ground quickly, and drainage is always good. Vixens use the surrounding forest for shelter and escape; they can sun themselves in the adjacent meadow and their rambunctious pups can play there.

A vixen may use the same whelping den year after year, and when she dies, the site may be passed on to one of her daughters. One fox lair near my cabin, for instance, has been active for nine of the last twelve years. Since adult foxes in the wild usually live only three to seven years, this den was probably occupied by several different fox families. On the other hand, abandoned lairs that deteriorate may be renovated by foxes after a long vacancy. The first den I ever studied in detail, in 1972, was active until 1974. After that, it lay vacant until a young fox couple reoccupied it and raised a family there during the spring of 1980.

Foxes never seem to rely on just the whelping den, however. In my area, they always have other, smaller burrows hidden away on their territory. If disturbed or threatened at the whelping site, the vixen or dog fox will simply move the pups to a new location. Frequently, the vixen initiates the move, which sometimes leaves her mate in a quandary.

I remember one such experience when, for an extended period, I was observing foxes at a den twenty-four hours a day in order to document how the six-week-old pups were being raised. One afternoon, in an attempt to get some photographs, I unwittingly crossed an invisible but important vulpine boundary, and the vixen reacted as if she had decided enough was enough. She waited until the middle of the night and then moved the pups, not carrying them as other canids do but marching them along behind her. About first light the dog fox returned to the den with a rabbit in his mouth. He went to the main entrance and called the pups with the rapid "wuk . . . wuk . . . wuk" chortle that foxes use, but no one came forth. Setting the rabbit down, he began to smell around the area. He apparently was able to figure out what had happened by the odors that remained on the ground. Sniffing the site thoroughly, he finally detected the trail that the vixen and four kits had taken through the forest. He returned to the den, hid the rabbit, and then began to track down his family, following their scent through the bush. On the other hand, I, not being blessed with the nose of a f spent the next seven days searching in v for the new den site.

But I am getting ahead of myself. I me backtrack and follow the pups throu their eventful early life. After a gestat period of fifty-two days, the kits are bo in my study area this occurs during l March or early April. The average lit comprises five whining, hungry mout but a litter of nine cubs is not uncomm Regardless of the size of the litter at bir some cubs usually die. The number t survive depends, among other thin upon the amount of food the adult fo can find on their territory.

When the kits are born, they are he less and weigh less than a quarter o pound. Except for their smaller size, th are remarkably similar to newborn coy

chmidt

uple of red fox kits, left, with their juvenile fur—a sandy-red coat—nurse outside their den. Young foxes suckle until are about five weeks old, at which point they start spending er periods outside the den and are weaned. Below: A pair der siblings play at fighting.

ıline; Animals Animals

d wolf pups—with one important ex-ɔtion. Even at birth, most young foxes ve a curious white tip on the tail. Red es retain this white tag throughout ir lives, and they are the only North ıerican canid species to show this dis-ctive marking.

During their first month of life, young es do not possess the brilliant red coat t is the hallmark of the species; instead, ir coats are charcoal gray. Foxes are the only canids with this feature. At th, the whelps of coyotes, wolves, and er species of wild canids are also aked with dark gray fur. As far as I can ermine, this special natal fur does not ve any physiological function. It may ve as camouflage while the young ıids remain in the darkness of the den. Fox kits grow slowly during their first v weeks; their eyes do not open until y are ten or twelve days old. During ly life, the vixen constantly attends m. In many areas, the vixen may ven-e out of the den after only two days, but ıorthern Saskatchewan she remains in-e constantly from a few days prior to th until the kits are approximately ten ys old. She is completely dependent on male for her food during this period. is he provides with regularity.

Why is the vixen unwilling to leave the kits? David Macdonald, who has studied red foxes extensively in Britain, suggests that the kits are so small and vulnerable during early life that the vixen must surround them with her warm body if they are to survive. This maternal protection becomes increasingly important the farther north one goes. At the time the kits are born, the ground in northern Saskatchewan is still frozen and covered with snow. The den is damp, and the air temperature inside is a chilly 32 degrees Fahrenheit or colder. The vixen acts literally as a thermal blanket, protecting the cubs in their frosty underground chamber. One could almost say she incubates them.

The vixen begins to leave the den and resume her normal travels when her cubs are about two weeks old. By then they are well furred and large enough to maintain their own body temperature. She now spends more and more time away from the lair hunting for prey for herself, but she continues to receive some food from her mate. And she does return to the den at regular intervals to nurse the kits. While in the den, she attends to her other maternal duties as well. She plays or naps with the cubs and then grooms them—cleaning out their ears, licking their groin regions, and eating their waste products. She maintains this routine until they are five weeks old, when she begins to wean them.

The early life of a kit fox is not the carefree, leisurely existence that one might imagine. It is business from an early age. During their second week, the kits begin to grow faster and their milk teeth start to come in—canines first, followed by incisors, and finally, premolars. During their third week, they begin to experiment with their teeth. They chew and suck on meat that the parents have brought them and learn to enjoy the juices found in a freshly killed rabbit. Now they enter an important phase of their development.

At this time, the fox kits are far from fully coordinated and have been aboveground only for short periods. Yet at about twenty-five days of age, they begin to fight viciously; they clash with each other in short, serious, and sometimes fatal contests. (Fatalities are rare, however.) Fox kits do not act like cute, cuddly puppies such as those of the domestic dog; rather, they have always seemed to me to have a slightly demonic character about them. They are tough, month-old thugs, little street fighters that initiate fights and, over a period of ten days, establish a strict dominance hierarchy. The alpha (or dominant) member of the litter establishes itself, and the process continues all the way down to the weakest animal.

Evidence suggests that these dominance relationships among the cubs remain stable and have a great bearing on their survival. If the adults are bringing the kits only a limited supply of food, competition for it is keen. By establishing a hierarchy, the kits determine who can steal food from whom. The largest member of the litter, whether male or female, usually becomes the alpha pup. Using either intimidation or direct attack, this animal steals food from its littermates. Each pup steals food from littermates below it in the hierarchy. It is a blunt fact of a fox's life that the dominant pups get a larger portion of the food and have the best chance of surviving, while smaller and submissive ones may perish. The runt of the litter usually dies first, then the second lowest in the hierarchy, and so on. It is a brutal process; but given the constraints of the hierarchy, it is the only way healthier kits can sur-

A red fox mother stalks a ground squirrel that ventured too far from its hole. The squirrel bolted, the fox leaped, and about ten yards later, the vixen had a meal for her kits. In fox families, both parents usually hunt in order to feed the young.

Brian Milne; First Light

vive. Nor have parent foxes evolved to interfere with this sibling rivalry, since the competition results in a litter composed of the healthiest whelps. Pared down, the litter size is also now in balance with the food resources of the territory.

By early May the fox kits in my area begin to come aboveground for longer periods of time. At this point, the hierarchy is solidly established and, with that crucial matter out of the way, the aggressiveness of the cubs actually diminishes. Gradually, they become more social, playful, and puppylike. It is at this time that most people first see young foxes. How much has happened in their lives before we are even aware of them!

When a parent fox returns to the den during early May and chortles for the pups, they stumble out—unsteady on their feet, blue eyed, and still dark coated. But at about this time an important change takes place: at about five weeks of age, they start to lose their dark natal coat and get a new pelage. Once again it is not the brilliant red of an adult fox, but a sandy-colored juvenile coat that almost perfectly matches the sandy soil of the den site. This coat helps to camouflage the pups around the den and protect them from occasional predators, such as hawks, owls, and coyotes.

Reflecting on the sandy-colored coat, I began to realize that this juvenile pelage had come about from an interesting series of events. I can imagine it evolving something like this: At first the vixen tended to dig her whelping den in sandy loam simply because it afforded good digging. But over time, the fur of the kits slowly evolved to match the soil's color. Evolutionary theory states that, if the sandy-colored pups have even a slightly better chance of surviving, all fox kits will eventually develop this coloration. As this happened, there was greater pressure on the vixen to locate her den in sandy-colored soil. Consequently, the selection of the den by the vixen and the juvenile pelage of the kits are coadapted to protect the young during their vulnerable first month outside the den.

This buff coat of the young foxes is actually a specially colored underfur (the underwool of adult foxes is a dark gray). The kits keep this juvenile coat for approximately five weeks, but starting in early June, outer red guard hairs begin to grow through. By the end of June, kits display the bright red coats normally associated with adult foxes.

When the kits are five weeks old, they begin the transition that will launch them into adult life. The pups now begin eating solid food, and the vixen starts to wean them. Weaning fox pups is an uncom
cated procedure. If the kits try to nu
the vixen rolls over on her stomach. If t
persist, she threatens them and runs o
short distance. She becomes increasin
unreceptive to their suckling, and by
time they are eight weeks old, the pups
completely weaned. But being wea

oesn't mean being cut off. The parents ontinue to hunt and scavenge at different mes of the day and night in order to upply the kits with sustenance. These dults bring in an assortment of prey nd present it to their pups. For example, n one week the menu included rabbits, nice, voles, squirrels, groundhogs, songbirds, grouse, and a spawning long-nosed sucker.

Distributing this food is a household ritual in a fox family and always happens in the same way. Carrying the item in its mouth, the adult fox arrives at the den, chortles, and one or more of the pups rush out to greet it. The first pup to reach the parent crouches low and beats its tail about wildly. The kit whines and creeps toward the adult and then reaching up, it smells, licks, and bites at the corners of the adult's mouth.

There seems to be a consistent rule in fox families that the adult will give the food to the first pup that begs for it. This

W. Ruth; Bruce Coleman Inc.

Below: An older kit (left) takes food from its parent (right) while another (center) waits for a chance to break in. Foxes clash violently with each other when still very young, setting up a dominance hierarchy. This determines which pup can steal from which and, if food is scarce, may decide which ones survive. When kits reach the age of nine or ten weeks, parents start supplying less food, as part of a campaign to make the youngsters more independent. Right: A parent checks the den.

Stephen J. Krasemann; DRK Photo

way, supplies are more or less evenly distributed. Basically, the hungriest pup keeps the best watch, gets to the parent first, and is given the food. However, once it has received its ration, the kit still has to defend its prize against littermates, either by running off or by threatening any siblings that come near. As I explained earlier, a dominant pup will frequently challenge and steal the provision from its subordinate littermate.

Food-begging behavior, by the way, also appears many months later but in a completely different context—as part of the submissive behaviors shown by adult foxes. When two full-grown animals meet, the subordinate fox often acts as if it were a young pup, begging to be fed. It crouches low, whines, and beats its tail madly in every direction. This keeps the white tip of the tail in constant motion (much like waving a white handkerchief) and lets it function as an attention-getting device. The subordinate fox slowly creeps up to the dominant fox and carefully reaches up to smell and lick the corner of its mouth. This use of infantile behavior by adults is not unique among red foxes. Embracing among adults, which is used as a greeting and reassuring gesture not only among humans but also chimpanzees and baboons, may be derived from infantile grasping. People in love sometimes coo and baby-talk to each other; we sometimes stammer or show shy juvenile behaviors when introduced to famous people.

The role of the dog fox in raising the kits has been debated among naturalists and field biologists. Some state that the male fox is never seen around the den, while others conclude that he supplies most of the food for the pups. There must be considerable variation among red foxes of different areas. The causes of these differences are not fully understood. But in Prince Albert National Park, an area where the foxes are almost completely protected from hunting and trapping, I have consistently observed male foxes bringing food to the pups until they are approximately ten weeks old.

In addition to the parents, other foxes will occasionally feed the pups. These "helper" foxes are an interesting phenomenon. Most often the assistant appears to be a daughter from the previous year's litter that has stayed on the family territory but not given birth to pups of her own. When she is present, she makes a definite contribution to rearing.

This helper illustrates an important point about evolution. Evolutionary theory states that individuals of a species that are most physically and behaviorally fit will leave the greatest number of o spring. But twenty years ago, British bio gist W.D. Hamilton stressed that an in vidual's relatives are also important. F example, red fox helpers are as closely lated to their full siblings as they would to their own offspring. If an assistant creases the survival rate of her young brothers and sisters, she helps some of h own genes survive into future generatio

Foxes that aid in raising their young brothers and sisters may also derive oth benefits. For example, they may gain e perience that will help them rear their o offspring more successfully. In a fe cases, they may also inherit part of th parents' territory.

Hamilton's theory makes another p diction about these young vixens. It sta that if food is scarce, the daughter w help raise and feed her mother's litt

wever, if food is abundant, the male fox breed with both the older vixen and daughter, and both vixens will raise lit- on the family territory. The male will g food to both litters, and the vixens, ead of competing, will tolerate each er. Why does the theory predict these nts? Because when food is abundant— sidering the genetic relationships in- ved—each fox will pass on more of his er genes to the next generation if mul- e litters are reared on the territory.

My field observations tentatively seem upport these predictions. In my study a, during years when prey was abun- t (one year, for example, there was a k in the snowshoe hare population), I occasionally observed two vixens ing separate litters several hundred ds from each other, and once, within same den. In both cases the vixens got along amicably and one dog fox brought food to all the pups. These observations suggest that the vixens were acquainted and may have been related. These preliminary data are interesting, but before we draw any final conclusions about this aspect of the fox's family life, more detailed research is needed.

During middle and late June, the pups' transition to adult life continues. They have grown to be nearly two-thirds the size of adults; they are fully coordinated and exhibit a bright red coat. During this period the parents start to visit the den less frequently, and the amount of food they bring starts to diminish.

At this point, as in many species, a classic conflict between parent and offspring arises. The fox kits appear perfectly content to remain at the den, play continually, and be fed by the parents. However, the adult foxes, which have been run ragged, seem to have some other arrangement in mind. And fortunately for them, they control the situation.

During June the pups wait endlessly for the adults to arrive with food. When an adult finally does appear, one pup gets the food, which he quickly consumes. Then the adult often takes one or several of the pups on exploratory trips away from the site. At first the parents lead the kits away and later accompany them home. But after a few of these excursions, the kits return on their own. I wish I could have gone along, but the parent foxes never tolerated me on the expeditions, and this aspect of fox life has always eluded me.

The kits, while hanging around the den, begin to eat wild fruit and to hunt insects and whatever other prey they can find. Gradually they become more confident,

venturing forth slightly farther each day and spending less time at the lair. Thus it seems that a combination of boredom and hunger eventually drives the kits away from the den site, whereupon they start a predatory, scavenging life of their own.

At first the pups travel in twos or threes. However, since the prey they hunt are small and quick, to capture one, the fox must hunt in a stalking, catlike manner using a surprise attack. These constraints slowly force the young foxes to become solitary predators.

Occasionally, the vixen and pups will rendezvous on the territory during late summer and early fall. When this happens, the foxes greet, play, and generally enjoy each other. By this point, however, the dog fox is intolerant of his cubs. During September, the male kits begin to mature sexually, and this increases the competition between father and son.

No one is certain what causes the kits to finally leave the territory altogether. Adult foxes have not been seen aggressively driving their young away, but they may exclude them from the best hunting and scavenging sites. Whatever the cause, during late September or October, the kits begin to disperse. Males leave first and travel the farthest. Each tends to travel in one direction until he has found an available territory. Once male kits have left their birthplace, they usually don't return. Female kits may remain on the family territory into December, and if food is plentiful, one or several female offspring may stay on.

Such is the way it happens. Each spring, kits are born; as helpless as embryos, they would freeze without their mother's constant attention. In the course of six short months, these tiny, helpless creatures grow into self-sufficient, graceful, flame-colored predators that leave their families and seek out their own part of the forest. When a young fox leaves, it becomes self-reliant and takes on the ways and manners of adults. It claims a territory and inhabits it with another fox—its prospective mate. During the frozen darkness of winter, the pair set up the territory and court, and the cycle inherent in a fox's life completes itself. □

These drowsing foxes have their second coat of fur—a sandy one—which matches the soil of the den site and therefore may protect them from occasional predators, such as owls, hawks, and coyotes.

So Grows the Tree

The misshapen shrub at tree line may be the same species as the spire-shaped conifer farther down the slope. Are their differences more than bark deep?

by Jeffry B. Mitton

At ten thousand feet on the front range of the Colorado Rockies, subalpine fir and Engelmann spruce stand tall and upright—classic examples of the spire-shaped conifers of alpine forests. Just a little farther up the slope at tree line, however, individuals of the same species have a markedly different look. Here they are called flag trees, because their stems are often so pruned by severe winds that limbs grow only on the leeward side; trees at tree line also have dense skirts of branches encircling the stems near ground level. Even greater changes in tree shape are apparent higher up the mountain slopes in the alpine tundra, where the trees have a dramatically altered growth form called krummholz, or elfinwood. Those trees grow both upward and outward but are so pruned by drying winds that they spread laterally, forming prostrate shrubs. Branches on the leeward side often put out roots, while wind and windblown ice crystals abrade and erode the windward side; consequently, the trees grow and move downwind, leaving a trail of wind-carved "driftwood."

Biologists have long known that wind and other environmental factors determine what form a seedling will acquire. There has been debate, however, over whether these differences in shape are accompanied by genetic differences. For evolutionary biologists, who strive to understand the conditions that produce adaptive genetic change in populations, change that may ultimately lead to the emergence of new species, the resolution of this sort of debate is important.

Genetic experiments with such slow-growing and long-lived organisms as trees have rarely been carried out, however. (Some mature trees at our site may be as much as 700 years old, obviously impractical subjects for tracking through several generations.) And until recently, evolutionary biologists who wished to monitor genetic differences in populations could track only such visible traits as color and striping in land snails or colors and spots in moths and butterflies. Evolutionary studies were therefore restricted to species that were small (so they could be kept in laboratories) and that reproduced rapidly

Extreme cold and severe winds at tree line (about 11,000 feet in the Rockies) force the normally tall, spire-shaped Engelmann spruce into a prostrate growth form called elfinwood, or krummholz. In this tundra region, the spring and summer growing season is only about forty-five days long, and many trees fail to produce pollen, seeds, or seedlings. In this event, branches touching the ground may put out roots, in an asexual mode of reproduction known as layering.

genetic variation could be watched
many generations). In the last few de-
es, however, techniques adopted from
ecular biology have enabled evolution-
biologists to study a much greater di-
ity of plants and animals.

)ne such technique, now in common
is electrophoresis. This laboratory
allows biologists to see genetic differ-
es among individuals by showing how
products of genes, the enzymes, differ.
enzymes are made of proteins, and cer-
genes are the blueprints for making
ific proteins. Remaining stable while
ıcing chemical changes in other sub-
stances, enzymes mediate myriad physiological processes essential to the growth and maintenance of all living things. When electrophoretic analysis is performed on a number of individuals in a single population, biologists can chart that population's pattern of genetic variation for a specific enzyme. It is not even necessary to know the enzyme's function. The beauty of electrophoresis is that it permits biologists to see, through enzyme staining, genetic variation that would otherwise remain invisible. This information allows an exciting, hitherto impossible look at the dynamic processes occurring within small geographic areas and within single generations, regardless of the size or generation time of the organisms being studied.

I have been using electrophoresis in the Rocky Mountains, attempting to discover some genetic pattern among the three growth forms (krummholz, flag, and spire) of Engelmann spruce (*Picea engelmannii*) and subalpine fir (*Abies lasiocarpa*). These are the most abundant trees around tree line (approximately 11,300 feet) on Niwot Ridge, a mountain research facility maintained by the University of Colorado on the eastern flank of the Continental Divide in the Rockies. The climate on the ridge is challenging. Although summer temperatures may reach 85 degrees Fahrenheit, winter temperatures have been known to plunge to −37, and eighty-mile-an-hour winds are not uncommon. Permafrost can be found below the surface here, and the growing season—defined as the time between the last hard frost of spring and the first hard frost of fall—is seldom longer than eighty-one days and may be as short as thirteen days. Snow may fall any day of the year.

In this rigorous environment the distribution and shape of trees are largely determined by wind, temperature, snowpack, and sunlight. Winter winds sweep the snow from exposed ridges, and drifts more than fifty feet deep pile up in troughs. At our tree line study site, biologist Peter Wardle demonstrated that exposed parts of trees are dried out and eroded by wind-blown ice crystals. Limbs buried in the snow are protected from extremes in temperature and are sheltered from the wind; but if the snow cover persists long into the summer, the needles are attacked by snow molds and the photosynthetic tissue is destroyed. Thus, some trees are harried by too little snow, others by too much. In the very harsh environment at the uppermost limits of tree line, trees often fail to produce pollen, seed, or seedlings. Here some species persist by "layering," an asexual form of reproduction in which roots form from branches that touch the soil.

The influence of snow upon the distribution of trees is most clearly seen in the ribbon forests of the subalpine regions. The trees in these forests act as snow

fences, and seedlings do poorly in both the wind-scoured areas upwind of the fences and in the deeply drifted snow glades in the lee of the fences. The resultant forest is not continuous, but is composed of narrow stands of trees at right angles to prevailing winter winds.

In the krummholz zone, above tree line, seedlings need the protection to get established. Here, they are most successful in the shade of existing krummholz and shrubs. It may be surprising that seedlings and saplings need shade in this cool summer environment. In fact, too much sun is one of the common causes of death for seedlings: if the surface temperature reaches 130 degrees, the seedling's cortex, which transports water and nutrients, is destroyed.

To determine whether the morphological differences observable at tree line Niwot Ridge were associated with gene variation, Michael Grant and I used el trophoresis to look at peroxidases, en matic proteins in the needles of Eng mann spruce and subalpine fir. C samples included krummholz, flag, a the common spire-shaped individu within each species. The results were same for both species: there were subst

John Ward

All plants capable of surviving at tree line keep a low profile. Left: A cushiony patch of alpine avens blooms among the krummholz forms of subalpine fir and Engelmann spruce on Niwot Ridge. Below: Ribbon forests, long stands of trees that act as snow fences, are the result of the combined effects of snow and wind.

David L. Buckner

enetic differences among the three lations, and in each species the pro- ons of the different kinds of peroxi- in the flag trees were intermediate een those of spire-shaped and mholz trees. The disparities existed though the sampled tree populations within a few hundred yards of each , so pollen could move easily among ee types.

Unlike the morphological differences, which are both conspicuous and environmentally created, the enzymatic differences among the three populations are not only hidden but are also the result of real genetic differences. What causes and maintains such genetic variation? Could it be chance? Probably not, because windborne pollen and seeds can easily move among the three populations, thereby evening out the gene ratios. Perhaps the force is natural selection, but we do not know how the various peroxidases influence plant survival in these three environments. Peroxidases perform many functions, among them protection of tissues against fungal infection. One possibility is that the alternate forms of peroxidases exhibit varying degrees of protection against snow mold, and the frequencies of the particular peroxidase genes thus may reflect the degree to which the trees are at risk of infection from this fungus. Unlike the chance hypothesis, this explanation does not deny that pollen and seeds may move among the three growth forms, but rather it suggests that natural selection, through differential survival of trees of different genotypes, plays the dominant role in determining the pattern of genetic variation across tree line.

On a hillside near the University of Colorado, another species of forest tree, ponderosa pine (*Pinus ponderosa*), also exhibits genetic variation, but here the pattern does not seem to be produced by natural selection. Yan Linhart and I and our students have undertaken a long-term study

The closer a plant grows to the ground, the less it is subject to the pruning effects of wind and ice. Right: The sparseness of needles and branches on the tops of these wind-sculpted "flag trees" testifies to the difference a few feet can make. These trees are on an exposed ridge slightly below tree line.

Tom and Pat Leeson

of 217 trees on the south-facing slope that forms the entrance to Boulder Canyon. We are monitoring genetic variation, reproduction, and predation. Age, growth rate, and seven protein genotypes are known for each tree. The production of pollen and female cones, as well as the level of infestation by insects and the intensity of browsing by deer, has been followed for the last seven years.

As in many other stands of ponderosa pine, the trees on this hillside are not evenly spaced. They grow in six clusters, each cluster containing fifteen to fifty-four trees. Although the six clusters are all on the same hillside and appear to share the same environment, they differ in some important characteristics. Among other things, the clusters vary in cone production; in any year, one cluster may produce ten times as many cones as another cluster of similar size. And although all of the trees appear quite similar to the human eye, herbivores discriminate among them and exercise consistent choices: the extent of deer browse ranges from 30 to 50 percent from cluster to cluster, and the level of woolly aphid infestation ranges from 9 to 49 percent. These groups also differ in gene frequencies for several proteins. In this case, the trees are clustered by genetic affinities, but this pattern of genetic variation is not conspicuously associated with variation in the environment.

A historical perspective can help reveal what is responsible for the clustering pattern. Photographs of this area taken a century ago show a much lower density of trees. The present clusters appear to be offspring of one or a few maternal parents in a small area and of an unknown number of paternal parents from a greater area. Much of the pollen from any given tree falls within several hundred feet, but some grains may travel on the wind for many miles. Ponderosa pine seeds are also carried by the wind, but most land very near the tree that produced them, within a circle with a radius equal to the height of the tree. Thus, clustering of genetic characteristics on this hillside probably corresponds to loose family aggregations produced by highly restricted dispersal of seed.

Like the krummholz spruce and fir that live more than a mile higher in the mountains, ponderosa pines at this site exist in a very demanding environment. They cannot produce seeds regularly. In the seven years for which recorded data are available, the annual production of cones by the 217 trees varied from zero to 17,900. Since a mature, healthy cone produces an average of fifty good seeds, it would seem that the odds of a new seedling getting started are very good indeed. However, an analysis of the ages of the trees (by counting the annual rings from small cores extracted from their trunks) revealed that seedling establishment was highly erratic. Sometimes no seedlings were established for several decades. Then there are occasional years, apparently salubrious to pine seedlings, when many new trees began long lifetimes.

An accounting of cone production by individual trees reveals that seed production is not a random event. Although the number of cones produced varies tremendously from year to year, there is some pattern. In most of the years for which data are available, a minority of trees (about 10 percent) produced most of the cones (from 64 percent to 92 percent). This imbalance in the reproductive performance may present natural selection with an opportunity to act. Analyses of prot genotypes, growth rates, and cone prod tion reveal that these three variables interrelated. Ponderosa pines that re larly produce many cones typically hibit lower-than-average growth ra Trees with certain gene combinati grow more erratically from year to y but produce cones in more regular nu bers than trees with other gene combi tions. Such interrelationships of prot type, growth rate, and schedule of production could only have been disc ered in long-term studies of ecological netics.

Both plant and animal studies have b efited from electrophoresis. Biologists survey about one hundred enzymes for netic variation, and ecological gene studies have now been conducted American eels on the Atlantic coast North America, starfish living miles neath the surface of the ocean, salam ders living high in the trees of tropical r forests, and cheetahs from the plains Africa. With the tools now in hand to c duct rigorous and comprehensive gene studies of the ways in which populati adapt to their environments, we are nea than ever to looking directly at the co plex and dynamic processes of evolutio natural populations.

A group of Inuit pose on board the schooner Era. *The ship's captain, George Comer, who served on whaling vessels in the Hudson Bay area of the Canadian Arctic, began taking photographs of Inuit life in the early 1890s.*

Mystic Seaport Museum

e Captain Back to the Bay

Photographs taken by a nineteenth-century whaling captain evoke memories among present-day Inuit

by Dorothy Harley Eber

"Quite often in the summer months we used to meet the Americans. You often heard people talking about them, so we knew who they were. They would be hunting for whales—beluga whales, bowhead whales—and walrus and polar bear hides.

"The Americans were mostly around Katitellik [Cape Fullerton]. They would winter there and then sail up toward Repulse Bay. My father was the man for the Scottish people so we didn't travel with the Americans—they had their own Inuit, Harry and his group—but I remember Captain Comer. We used to call him Angakok [the shaman] because he was able to take photographs. They would appear just like that, out of a piece of paper."

The speaker is Joe Curley, of Eskimo Point in Canada's Northwest Territories, born, he tells me, "not in the 1900s but in the late 1800s," when the Inuit (as the Eskimo here prefer to be called) pursued the bowhead whale from small boats among the ice floes for American and Scottish whaling vessels in Hudson Bay. His uncle and adopting father, Anutimarek, or Scotch Tom, was a chief of the Aivilik, the hunters who, for the fifty-five years (1860–1915) that constituted the whaling era in the bay, put their skills at the disposal of the foreign whalers. As we talk about those distant days and the personalities of the time, spread out on a table in front of us are copies of the photographs that gave Capt. George Comer, one of the great American whaling masters, the nickname by which he is still recalled up and down the west coast of Hudson Bay.

"He had a camera he would cover with a cloth," Curley continued. "He had glass negatives. He brought in various pieces of equipment and that's how he started taking photographs of the Inuit. People thought he was a shaman. An Inuit knows a shaman as a person who is able to make things appear or happen in a way no ordinary person can. If he had not produced these magical things they would not have called him Angakok. He didn't mind; Angakok was his nickname. But people didn't respect him so highly as a shaman that they weren't able to talk to him. They could have a normal conversation. They made friends with him and he used to eat amongst them. They favored him a lot."

In 1983, under the auspices of the Canadian Ethnology Service of the National Museum of Man, in Ottawa, I visited the new small towns on Hudson Bay's west coast, where the Inuit have made their homes since the erosion of the camp system. My purpose was to meet and interview descendants of the Inuit whalers, as well as the very few people still alive who, in their youth, sailed on the last of the whaling vessels. My talks were made possible by the bilingual generation of young adults who had attended school. For the interviews with Joe Curley my principal interpreter was a granddaughter, Madelaine Napayok Anderson ("At school English was my favorite; I like a proper past participle."). Later the tapes were carefully checked by Rosie Aggark, a daughter who works for the Interpreters' Corps.

In preparation for my trip I obtained prints of a number of Comer photographs. The captain had worked closely with Franz Boas, the "father" of anthropology, and had helped build up arctic ethnographic collections for a number of museums, including the American Museum of Natural History. According to Fred Calabretta, who made a study of the captain's life for the Mystic Seaport Museum in Connecticut (one of several institutions that hold important collections of the photographs), Comer began to use a camera in the Arctic as early as 1893. Calabretta has been able to locate at Mystic only two images definitely predating 1900; but hundreds of other photographs survive, taken in igloos, forecastles, and in all arctic weathers while Comer whaled with the *Era* (1897–1905) and the *A.T. Gifford* (1907–12). The task was not easy. In the *Era* journal for February 1, 1904, Comer wrote of the difficulty he experienced in photographing Inuit in the *Era* cabin: "The first flash light I probably did not fix right as it came near taking the roof of the cabin off—at least the report sounded loud enough to have done it."

As I visited the new Keewatin towns (the Keewatin coast borders Roes Welcome Sound, the principal Hudson Bay whaling theater), the photographs were al-

Captain Comer's picture-taking ability made him known to the Inuit as Angakok (the shaman), "a person who is able to make things appear or happen in a way no ordinary person can."

Mystic Seaport Museum

ways popular exhibits and provoked many stories. As informants told about spring whaling, about bringing ice blocks to the whaling vessel in winter, the scenes their words conjured up were often there, visible in the pictures.

Among my pack of pictures were many of people: groups, families, and especially images of a man and his wives. (In Comer's time most Inuit men had two wives. "Oh it was necessary for a great hunter—he needed two wives to work on his skins," one woman told me.) And many times I heard what good friends the wives in a family had been. "My grandmother used to joke with her husband-sharing partner about how, after they died, they must have their boxes close together. They had been great friends in life and wanted to stay together," another woman explained. Still another told of the additional hea break that followed the death of the m of the family. "My grandmother cr when my grandfather's other wife was ing to another family; they didn't wan be separated."

Most of the people in these poign studies were identified, but generally o by the names the whalers had bestowed them. "The people here would still rec nize their own relatives if their real nar had been used," I was told. Wrapp tongues around Inuit names was a pr lem for the foreign whalers, so they sorted to their own system of nomen ture, handing out common English nar (Charley, Mary, Harry) or names t identified helpers with specific ships captains or odd nicknames: Starbo Eye, Bye and Bye, John Bull, Jumbo, Stonewall.

Apparently perplexed by the sa problem, the Inuit, too, went in for nar calling. "The whalers weren't too fu about names in those days; so by w they were doing, so they were called, was explained. Physical characteristics ten inspired Inuit names for foreign The well-known Scottish captain J Murray, for whom Joe Curley's adopt father worked, was known as Nakuna (Cross-eyes).

While the names the foreign wha had bestowed often made it difficult learn about the sitters in Comer's ph graphs, fortunately, some of the nam perhaps the most unusual or those give the most distinguished Inuit whalers, w remembered. Some are still in use, so times in corrupted form.

Almost everyone was aware that Sh fly was the whaling name of Nivisena Comer's close companion, who alw traveled with the captain on shipboa The mere mention of her name spar lively comment wherever I visited up down the Keewatin coast. "Her capt gave her that name because she was ways shooing away the flies," an in mant explained. She was one of the wi of Tugaak, known as Ben, but liaisons tween Inuit women and the *kadl* (white man) were commonplace and cepted. Ben "knew the captain

f a number of photographs of Tom adopted when he was a little boy by r's Inuit companion, Shoofly, and d after the owner of the ship Era. *ortrait was entitled* Tom Luce at ller, July, 1905.

port Museum

enark as a girlfriend, but they were ood friends to each other." When lied, Comer recorded in his diary e helped with the burial. Shoofly ap- in a number of Comer's photo- s, sometimes identified, sometimes ut often recognizable by the two ificently beaded parkas she is known e worn.

Rankin Inlet I called upon Shoofly's daughter Bernadette Ookpik Pat- born about 1917, and her husband, oe's ancestors, too, were whalers; his worked for the Scottish captain Murray. Joe has a whaling name he ted—Coopie. It comes from coffee. ting a Scottish accent he says, be every morning the whalers would ut 'Coofie! Coofie!' "

nadette Ookpik, known as Ookpik ot her first name from French mis- ies), is the daughter of Shoofly's iological son, Oudlynnock, or as the rs called him, John Ell (from John llivan). John Ell participated in arctic expeditions and was said to be st known Inuit of his generation. He nd wrote English, played chess, and nd developed photographs. Inuit I to often referred to him as Comer's n and some declared he was Com- ctual son. Ookpik does not consider this likely. "Yes, my grandmother had a captain friend," she told me. "In fact she had pictures of the captain and used to receive presents of clothes and checks. But it was after John Ell was born that Angakok was living with Shoofly. My grandmother could bear no more children. She had to adopt them. John Ell had no *kadluna* blood. He was a true Inuit."

Ookpik and her husband are proud of the great reputation that Inuit hunters earned during the whaling years. (Up here they remember that the Inuit "caught more whales than the *kadluna*.") "I've heard," she says, "that some of the Inuit whalers were really good. In the whaleboat they used to have an Inuit for captain. The tradition was you'd take the man who had the most experience and let him be the leader."

Ookpik had her own picture of her grandmother and brought it out to show me. It was from a folio of old photographs of Inuit life published by the Northwest Territorial government; the photograph is not by Comer but by A.P. Low, commander of the Canadian government expedition vessel *Neptune*, which wintered beside the *Era* at Cape Fullerton in 1903–04. Picture-taking apparently enlivened the long winter.

In Low's shot, Shoofly's appeal is evident. She wears her long hair in laced braids in the manner northern educator George Diveky says indicates a woman has borne a male child. She is wearing her most famous *amoutik*—the women's parka with a pouch for carrying a baby—purchased by Comer in 1906 for the American Museum of Natural History. On the front, beside the designs of high-heeled boots and compasses, her name Shoofly (hidden in the picture by her braid), is embroidered in white beads. On the back of the parka, a kneeling hunter takes aim at a caribou. Low also photographed Shoofly with a group of women on the sleeping platform of an igloo. In this picture Shoofly is wearing a borrowed *amoutik*. An Inuit woman showed me a much treasured copy of this photograph that had been sent long ago to her grandmother and explained that Shoofly had dressed up for the camera in the grandmother's *amoutik*.

Ookpik told me that she had once possessed some parka decorations that had belonged to Shoofly. "My grandmother gave her *amoutik* decorations to her daughter-in-law. My mother had them, and later they were given to me. But they got lost. I actually had them, but at the time we were moving to the mainland from Southampton Island and we had to leave much of our stuff behind because we had only a small boat. I never saw them again. I heard they were given to an older person. All I can remember of those decorations are the bands for the sleeves. The beads came from the whalers, and it was the desire of every young girl to have an *amoutik* like that."

During an interview farther up the coast in Chesterfield Inlet (here in 1912 the Catholic oblates established the first mission among Hudson Bay Eskimo), I discovered that in our pack of photographs we had a picture of Shoofly's sister. Leonie Egalak Sammurtok exclaimed with delight when she found a photograph of a young woman identified only as Jumbo. "Jumbo! She was my aunt. Her Inuit name was Kognataluretuk." Jumbo was born into the same family as Shoofly but was then adopted into Egalak's family. "I used to see a lot of her," Egalak con-

Shoofly, who lived on board the Era *with Captain Comer, was also photographed by A.P. Low, commander of the Canadian ship* Neptune. *She is shown wearing an elaborately beaded* amoutik*—a parka with a pouch for carrying a baby.*

Public Archives Canada/PA 53548

tinued. "She used to be lots of fun. She was tall and very fat and her whole body used to shake because of her pounds. My grandmother and my mother used to tease Jumbo a lot because, compared with them, Jumbo was very fat. 'You should be slim, like us,' they used to tell her."

Looking at the beaded costumes in the photographs caused Leonie Egalak to remember a beaded parka she had worn the year before she began living with her husband. "I once had a costume with beads that was not quite a proper *amoutik* but that was rather heavy. It was before I had children. In those days the Inuit had various ways of making clothing, and just as little children would wear overalls we used to make a special parka for young girls that was not for carrying a baby. It was almost like the regular *amoutik*—it had all the regular fringes but it had a longer and the tip of this used to turn up in just to your heels. Later on when young woman began to bear children would get the proper clothing for carry a baby. I wore the parka only for a y then my mother asked the beads back my sister."

In Chesterfield Inlet, I was able to firm another important identification reasonable certainty. Viewing Com fascinating series of photographs take side igloos, a number of people, inclu a missionary, recognized Siatchiak important Inuit whaler known to the eign whalers as Bye and Bye) in one of photos. He had died in the mission's ho tal. W.O. Douglas, a sergeant in charg the Royal Canadian Mounted Police tion at Cape Fullerton, described Bye Bye's prowess in an article in *North* m zine about a whaling expedition with Eskimo skipper about 1919, after American and Scottish whalers had g "Bye n' Bye, I soon discovered, was perb whaling skipper. Bye n' Bye sho orders in a mixture of Eskimo, Eng and whaler jargon and every man did actly as he was told.... The skipp warnings about what he would do to one who made a noise were almost as t fying as some of the yarns I had h about the destructive power of a wh thrashing tail."

Within an hour, Bye and Bye and crew took two bowhead whales, an traordinary feat. "The whales were chored to the ice and cut up at the edg the floe.... I shall never forget the s of a man going down a ladder inside carcass and sending up pieces of heart liver with a block and tackle," Dou wrote.

Southampton Island is where man the Inuit whalers settled in the last da whaling, encouraged initially by Co who in 1908 left the greater part of Inuit crew to winter there. Today m descendants live in Coral Harbour, only community on the island. Kar Bruce is the granddaughter of Me ("the American") Aussaar, a nephe the Inuit chief Harry, who made draw and carvings for Comer. "He was no

port Museum

ellow," Kanyuk remarked, looking mer's impressive photograph. Her nd, Mikitok Bruce, is a son of Tom who was adopted by Shoofly when a little boy. Named after the owner *Era*, Tom Luce was the subject of of Comer's most appealing shots.

"Angakok was a very likable man," ak told me, drawing on stories she eard. "He got his name because of otographs and because he had those echnical things that would wind up. here never used to have those me- al things. Every so often Harry was l to dinner with the Captain and n turn Angakok would share with uit and eat some seal meat."

ry, whose Inuit name was Ipatok ') Tasseok, appears in many of the graphs, sometimes with his Inuit on shipboard or in a snowhouse, mes alone wearing one of the plaid Joe Curley remembers as the type owned by those who worked for the cans. And Harry, along with his Powty, starred in a series of photo- s that showed the techniques sha- used in their contacts with the forces spirit world. In the whaling days ns were powerful indeed—"they summon a ship when people were ng"—and whaling captains had great respect for their powers. Although today the Christian Inuit sometimes do not like to remember or talk about shamans, most people found these photographs of considerable interest, and informants gave slightly differing versions of activities depicted. Looking at the picture of Powty lifting Harry's head with what appears to be a leather thong, Joe Curley said, "This person's head may become so heavy it is not possible to lift it. They will ask this person what his head contains—they will ask many different questions." Of the shaman tied in ropes, Curley said: "This person is tied up completely but because he is a shaman he will be able to free himself."

On seeing the same photograph, Joan Attuat of Whale Cove supplied some additional information. "Here you see there are witnesses watching to make sure the shaman tells the truth, that he is truthful about what he says he does. The person bound will have the witnesses with him at all times, to make sure there is no trickery. They will hold on to the rope that ties him."

After my visit to Coral Harbour, I began the journey back to Rankin Inlet, where I was to catch a plane out of the north. While there must certainly be Keewatin Inuit I did not interview who would

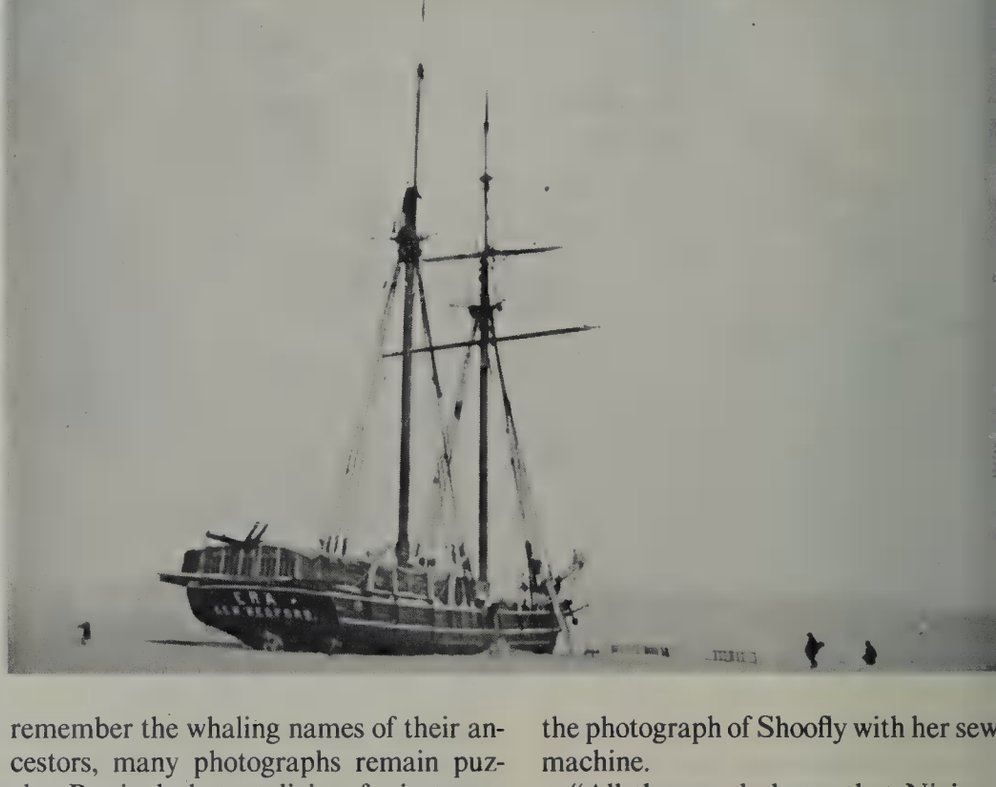
A starboard quarter-view of the whaling schooner Era *in the ice of the Canadian Arctic. Both American and Scottish whaling vessels plied the waters of Hudson Bay from 1860 to 1915, the years that constituted the bay's whaling era.*

Mystic Seaport Museum



remember the whaling names of their ancestors, many photographs remain puzzles. Particularly tantalizing, for instance, was a photograph of two young women and a child that Comer titled *Eskimo Gals*. "It's just my feeling," said Joe Curley, "that these are Uvinik's wives." Although there was no real evidence to support the identification, the photograph evoked a story of tragedy. Several of those who saw the picture wondered if the two beautiful young Eskimo women might be Hakaluk and Ikoak, wives of Uvinik, who were crushed to death in a terrible accident in the dangerous currents off Wager Bay about 1913. Many members of the family crew of the whaling boss Harry perished in this accident, and Uvinik, Harry's adopted son, later shot himself in his misery. The accident probably happened after Comer had departed from the north on his final whaling voyage, and it spelled a tragic end to the whaling days for Harry's Inuit crew.

In Rankin Inlet I saw Joe and Ookpik Patterk again and checked a few points with regard to the photographs. And on Ookpik's suggestion, I paid a call on Eugenie Towtoonee, a lively older person Ookpik believed would "have some historical material." Towtoonee had known Shoofly and was particularly taken with the photograph of Shoofly with her sew machine.

"All the people knew that Nivisen [Shoofly] was the first to use a sewing chine in the north. She was really g and could sew really well. She started s ing cloth material for friends and r tives—that's when we started using cl for clothes. I'm not sure what kind of cl exactly—I've heard she used to m dresses out of thin cotton. She used make them on the ship. The captain m have taught her how to make a pattern dresses and she started making dres and skirts. Maybe they had the cloth terial on Baffin Island or in the Ar Quebec region, but people remember t it was Nivisenark who started the clothing up here."

Shoofly is remembered as a pioneer trend setter in another sense, too. As the custom, she adopted a number of c dren. "Nivisenark bore only one child she adopted more children from other p ple," Eugenie explained. "Inuit ad children because they know they will g old and become sick. If her oldest son happened to die she would have had child to care for her; so she adopted so would have some support and help. adopted children who were half and h Probably she was not the only one

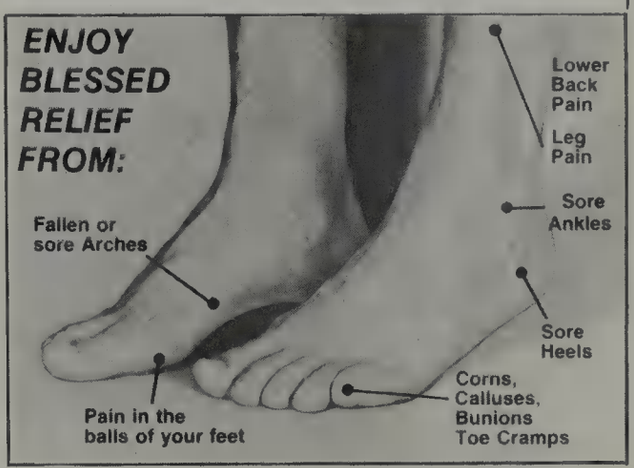
Here's How to Stop Foot Pain *INSTANTLY!*

There's really no mystery about what causes foot pain

Each of your feet has 26 different bones held in balance and position by tendons, muscles and ligaments.

Once something happens to destroy this balance, (no matter what your age) you experience painful feet, unless you do something about it.



There's really no mystery about finding relief

Since 1948, over 3,000,000 people are enjoying blessed relief they never thought possible . . . thanks to Flexible Featherspring® Foot Supports which are made in West Germany.

How do Featherspring bring relief? Well, unlike costly special shoes, mass-produced arch preserves, or ready-made, drug store remedies, custom-formed Flexible Featherspring actually restore and maintain the elastic support your feet had when you were a youth.

No matter how long you've had foot problems—be it 3 months or 30 years—the instant you slip a pair of Featherspring in your shoes (one pair is all you'll ever need)—you'll be able to stand all day, walk, dance, even jog or run in total comfort.

Featherspring act as a shock-absorbing, pain-relieving system which structurally realigns your feet. Not only do they restore the natural balance of your feet, they allow your feet to flex normally in all types of shoes. Thanks to Featherspring, your aching feet get the continuous, moving support which brings that relief.

There's really no risk involved in finding out whether Featherspring can relieve your foot pain

We're so certain that Featherspring Foot Supports will end your foot problems that if you're not completely satisfied . . . we'll refund your money in full . . . with no questions asked.

Write us for full information, there's no obligation and no salesman will call. Just fill out and mail the coupon below.

What people say in unsolicited testimonials, about Featherspring:

"Retiring as a golf professional was my own decision. Being forced to stop playing altogether was something my sore aching feet forced me to do. It got to the point where I would play a few holes and have to quit . . . because of my feet I just couldn't go on! I had tried everything and nothing seemed to work. Now, thanks to Featherspring my feet are absolutely pain-free and I finally got a spring in my step again."

Jock Hutchison, Jr. Northfield, Illinois

". . . I have thoroughly enjoyed the comfort Featherspring have provided me. You would not believe the difference they have made my feet feel-before I had such pain when walking because I have severe callus' on both of my feet."

Catch Our Great Outdoors Adventure!

A Slice of Paradise

In three large provinces and one vast territory, Canada's Adventureland is awesome—breathtaking—waiting to be discovered.

Serene and soul-stirring one moment, it can be excitingly heart-pounding the next. Here, you'll experience just about everything you ever wanted in a memorable vacation: unique, modern cities... storybook and frontier towns...a cultural mosaic found nowhere else in the world...heartwarming welcomes at every turn...a haven of exquisite and bountiful flora and fauna...and countless out-door adventures!

It's a world many people thought had disappeared. Yet here, right on America's doorstep, is a slice of paradise which has never been spoiled!

Go for Adventure

Make your vacation as tame or as wild as you like! Imagination and time are your only limits. And with so much to see and do, you'll never do it *all* in one lifetime!

Experience a Manitoba farm vacation, where you and your family can share the day-to-day lives of friendly people who live the Adventure year-round.

Camp or picnic just about anywhere—by a bubbli stream or an isolated, tranqui ...shared only by calling birds moose or majestic towering fi

The fishing is superb—leger —in Manitoba, Saskatchewan the Northwest Territories! Th are a lot fewer people and a lo more room. More lakes and w ways (some right beside highv More fish. More privacy.

Saddle up for fabulous trail riding in Alberta and "push b the frontier"...with a guide.

Toward Indian Nationhood

by Wilcomb E. Washburn

THE NATIONS WITHIN: THE PAST AND FUTURE OF AMERICAN INDIAN SOVEREIGNTY, by Vine Deloria, Jr., and Clifford M. Lytle. *Pantheon Books, $11.95; 293 pp.*

Vine Deloria, Jr.! The name—to some contemporary white Americans—conjures up emotions similar to those raised in the nineteenth century by the names Geronimo and Red Cloud. For many years Deloria, with his pen (and now with his word processor), has struck terror in the hearts of snooping anthropologists, guilt-laden editorial writers, obtuse historians, and others who grapple with the contemporary or historical Indian, whether as an economic "problem," a literary symbol, or a political force.

The secret of Deloria's success in becoming the preeminent Indian spokesman is his inexhaustible energy, his wry good humor, his not inconsiderable scholarly gifts, and his diplomatic skill. Deloria has his detractors among Indians and whites, but his critics have had amazingly little success at shaking his self-confidence or denting his reputation. In the present volume, as in the earlier *American Indians, American Justice*, Deloria shares author credit with Clifford M. Lytle, his colleague in the Department of Political Science at the University of Arizona. The partnership, unequal though it may be, is fruitful. Lytle's participation seems to have added depth and responsibility to the sparkling, cynical, but often careless approach that characterized some of Deloria's earlier works, such as *Custer Died for Your Sins*.

There are two books here. One, sober and scholarly, deals with the Indian past; the other, imaginative and speculative, deals with the Indian future. The first "book" is a detailed consideration of the Indian Reorganization Act of 1934; the second deals with the recent and as yet not fully defined Indian struggle for a new identity. The two sections are appropriately joined under the felicitously chosen title *The Nations Within*, which signifies both the achievement of self-government under the Indian Reorganization Act and the current movement toward a national (and international) Indian identity.

The first part—a well-researched, general study of the bill that, under the guidance of Commissioner of Indian Affairs John Collier, completely reoriented the federal government's conduct of Indian affairs fifty years ago—does not seek to match the scholarly detail of earlier studies of Collier and the Indian Reorganization Act by such scholars as Kenneth Philp, Lawrence Kelly, and Graham Taylor. But while *The Nations Within* is popular and readable, it is not unscholarly except where the reader is asked to accept on faith the authors' attribution of motives. For example, the authors allege that Sen. Sam Ervin attached the Indian Civil Rights Bill to a fair housing bill in 1968 in order to kill the housing bill—a strategy that, if it did exist, was unsuccessful. This speculation is presented without any citation of authority or tangible proof. Some will accept the authority of Deloria on such matters because of the prominent role he played as executive director of the National Congress of American Indians from 1964 to 1967 and because of his influential role and continuing access to both Indian and white political leaders before and after his tenure as head of this organization. But such personal reminiscences are unreliable guides to the past; they smack too much of the journalist's shaky sources, which may be the raw m terial but not the substance of history.

In contemporary America the journ ist's role is often that of advocate, a Deloria and Lytle have too openly sumed this role. This is particularly tr when they move on to consideration o "movement toward nationality" on t part of Indian tribes.

Because special interest, sympathy, a guilt are inextricably mixed in all cons erations of the American Indian, it is di cult to obtain an unemotional, realist and impartial assessment of such a volat subject as Indian sovereignty. Desp their sophistication, the authors fall i the trap of judging John Collier's achie ment (in getting Congress to pass the dian Reorganization Act, which esta lished the legitimacy and defined t powers of Indian self-government as an tegral part of the law of the land) by ideal, rather than a practical, standa Collier is judged, not by what he wrest for the Indians from a sometimes u comprehending, sometimes skepti Congress, but by what he failed to obta such as a formal declaration of Indian litical sovereignty. Neither Deloria n other critics of Collier consider the prob ble fate that Collier averted: the total struction of Indian tribal identity and s ereignty. To say that Collier's legislati struggle "in most respects represented solid defeat" because the final version d fered radically from the original propo is to miss the forest for the trees.

The publisher claims that, in addition their analysis of the Indian Reorgani tion Act,

Deloria and Lytle trace the rise of Indi militancy and the decline of tribal gove

ment into near welfare-agency status, and show the political effects of Reagan's crippling budget cuts. They conclude with a set of sound proposals that take into account current economic realities while suggesting how traditional institutions can be used to resurrect sovereignty today.

Alas, if only publishers' blurbs would correspond to objective truth! Deloria and Lytle give a too-sympathetic account of the militant activities of the American Indian Movement (AIM) radicals at Wounded Knee and elsewhere, but fail to demonstrate that these actions have advanced the cause of Indian nationhood and sovereignty. The authors ignore the "work" of Leonard Peltier (about whom Peter Matthiessen wrote an entire book, *In the Spirit of Crazy Horse*, in 1983), the AIM activist currently in prison for shooting two FBI agents at Wounded Knee in 1973. Peltier has virtually become a patron saint of AIM, and his plight has been cited by the Soviet Union to blunt Western criticism of Soviet treatment of Andrei Sakharov.

Neither do the authors of *The Nations Within* do more than allude to the radicals' indictment of the United States for alleged crimes against humanity, such as genocide and sterilization of Indian women, before the Russell International Tribunal. Deloria is too honest a scholar and too sophisticated a politician to defend the radical Indian positions on s issues, which have little or no merit. he makes use of the radical rhetoric to press the vague hope of Indian lea such as himself for an evolution of In self-government into full Indian "nat hood."

Deloria is equally vague as to the pra cal steps that must be taken before In nationhood is achieved. He wistfully ludes to the "famous Twenty Points" which he was a principal author) sented to White House officials Leon Garment and Bradley Patterson du the 1972 election-week March on W ington. These points, which included toration of constitutional treaty-mak authority and the provision that all I ans be governed by treaty relations, v so totally out of touch with reality they had no chance of influencing the bate on Indian policy. After trashing Bureau of Indian Affairs (which now, cautionary measure, no longer exists separate, identifiable entity in Wash ton), the 1972 protesters and looters v provided tickets, at taxpayer expense return home. Had Collier not erected s a powerful protective shield around dian tribes by engineering the passag the Indian Reorganization Act, the w backlash that followed this ill-conce "protest" would probably have elimin whatever remnants of tribal self-gov ment had continued to exist.

Equally futile were the 206 recomm dations issued in 1977 by the Amer Indian Policy Review Commissio staffed almost exclusively by Amer Indians—whose principal recomme tion, as Deloria wryly notes, was for "n money." It seems never to have occu to the Indian leadership—such as it and is—that recommendations desig to wring power, money, and support f the non-Indian majority of the cou must have some relationship to poli reality.

Deloria and Lytle fail to provide cific recommendations for smoothing route from self-government to nationh The authors call for retention of In cultural values, reconciliation of facti elements within Indian communities, so on, but leave largely unspecified the ture of the Indian identity, economic tem, and political character that is pected to emerge. Recommendations phrased in party convention languag encompass everything, please every and offend no one. Thus Deloria and L assert that "relations between the t and the federal and state governm must be stabilized, and mutual res and parity in political rights must be

d." Yet the authors are belittling references to the "government-to-ıent relationship" that underlies ıt Reagan's Indian policy. The au-sert incorrectly that "the ideology y adopted by Republican admin-ıs . . . makes Indians wards of the ıent. . . ."

ia and Lytle also seem to think calling something by a different ne creates a different reality. Call-bal council a national council does ximize tribal sovereignty (even if ands the membership) or cause it ercised "in a more comprehensive ." Calling policemen peace offi-es not constitute a "structural re-of the police function." Resolving differences between "traditional" odern Indian tribal governments be accomplished with pious plati-easy criticism of elected tribal of-Most curiously, the authors do not have a substitute for elective gov-t by majority rule, the bête noire of litionals and radicals.

n claims against the U.S. govern-djudicated by the Indian Claims ssion, Court of Claims, and the upreme Court, constitute particu-nsitive issues among Indian lead-ers. Of all the land claims, the Sioux claim is the most famous. The Sioux are still divided on the question of whether to accept the 1980 Supreme Court decision replacing a series of earlier judicial determinations of the amount of compensation the United States owes the Sioux for the taking of the Black Hills over a century ago. Deloria, a Sioux, does not tell us where he stands on the issue, preferring instead to straddle it. As he notes, "Claims are both satisfying in terms of fulfilling ancient promises and disruptive in that they take an inordinate amount of time and energy away from other reservation activities that would be more profitable in the long run."

When all is said and done, Deloria and Lytle, while not providing a practical solution to the Indian future, have laid the basis for a more mature consideration of that future by Indian tribal leaders. They have done this, first of all, by providing a well-written and basically accurate consideration of the Indian Reorganization Act. They grudgingly give John Collier credit for what he did accomplish, even while chiding him for not doing more. Secondly, they recognize that the act is the fundamental and indispensable foundation on which the movement toward Indian nationhood, if it is ever to occur, must be built. Thirdly, they point out that a successful movement toward nationhood for all Indian tribes must be sustained by rhetoric that is pro-Indian rather than anti-white. "Self-determination involves having a responsible group that has pride in itself but does not generate this pride by pointing out the shortcomings of other groups."

The Nations Within takes a significant step toward creating this responsible approach. Whether the Indian nations will achieve the full extent of the sovereignty that the authors visualize is, however, doubtful.

Wilcomb E. Washburn is director of the Office of American Studies at the Smithsonian Institution and the author of a number of books on the American Indian, including The Indian in America *and* Red Man's Land/White Man's Law.

Erratum: An incorrect credit line appeared with the reproduction of Claes Oldenburg's "Proposal for a Cathedral in the Form of a Colossal Faucet" (November 1984, page 20). Permission to reproduce was granted by the Whitney Museum of American Art.

Venus Shows Off

by Thomas D. Nicholson

After months as a not too prominent evening star (bright enough but not well placed in the sunset sky), Venus is now glorious in the west after sundown, visible for nearly three hours. It improves as it goes past its greatest easterly elongation toward greatest brilliancy in late February, so we have a number of weeks of good viewing ahead of us. Mars, Jupiter's companion of November, is now near Venus, and both nearly keep pace as they move left through the stars this month. But Mars does close slowly with the brighter Venus. After dark each night, while Venus is still up in the west, look below it for Mars, the only bright object nearby. Watch throughout the month as it moves toward Venus. They will be especially prominent near the moon on the 24th.

Jupiter goes over into the morning sky at mid-month when it passes conjunction with the sun. Saturn improves as a morning star in January, rising about three hours past midnight at mid-month, well up in the southeast by dawn. It is in Libra, to the right and above Antares, the bright reddish star of Scorpius. The moon guides you nicely to that star on the morning of the 17th.

Events in the calendar below are given in local time unless otherwise stated.

January 1: The early evening moon, in Aries and about two days past first quarter, lights the sky until after midnight.

January 3: Mercury is at maximum distance to the sun's right, favorably located as a morning star low and to the right of the rising sun before dawn for the next two weeks. The earth is at perihelion, nearest the sun.

January 3–4: Aldebaran, in Taurus, is below the moon both evenings. Nearby are the V-shaped Hyades and the fuzzy patch of stars called the Pleiades, both dimmed somewhat by the moon's light.

January 6: Full moon is in Gemini. The twin stars to its left are Pollux and Castor; Orion's prominent stars and the two Dog Stars stand out below in the bright moonlight. The latest sunrise of the winter occurs today; morning light will brighten noticeably earlier in a few days.

January 9: The moon and Regulus, Leo's bright star, rise nearly together, climbing up the eastern sky before midnight. But the moon rises nearly an hour later each night and Regulus rises four minutes earlier.

January 11–13: The moon spends these three nights in Virgo, at perigee (nearest the earth) on the 11th; last-quarter phase on the 13th will be at 6:27 P.M., EST. It steadily approaches Spica, the brightest star in Virgo, passing above it on the evening of the 13th, when both rise at just about midnight.

January 14: Jupiter ends its recent reign as an evening star and technically becomes a morning star when it passes the sun (conjunction) today. It will reappear in our sky in a few weeks.

January 16–17: The late crescent moon now belongs to the morning sky, joining the stars and planets to the sun's right. It is close to Saturn before dawn on the 16th and to Antares—Scorpius's bright star—on the 17th. When it nears Jupiter on the 20th, however, both will rise only a few minutes before the sun, excluding any chance of our seeing them.

January 20: New moon, at 9:28 P.M., EST, is in Capricornus.

January 21: When Venus reaches greatest easterly elongation (maximum distance to the sun's left), it is best as an evening star. But not all elongations are equally favorable. Today's is a good one, if not the best. Venus is high and bright in the sunset glow and early darkness for several hours; the dimmer, ruddy-looking object near it is Mars. Venus's evening appearance can be enjoyed from now until mid-March, when it sets too soon after sundown for successful viewing.

January 22: The new crescent moon should surely be visible if the sky is clear tonight after sundown. High and to the sun's left, a slender crescent of sunlight bounces off its right side. Over the next several nights, it will move closer to Venus and Mars, above to its left, as the crescent grows thicker.

January 24: The moon passes below Venus and Mars in the early evening, making for a pretty sky if the weather lets us see it. The two planets are above the moon to its left. After the moon passes Venus (about

7:00 P.M., EST), it moves slowly to the left (but fast enough for viewers to notice the change in about half an hour) between the two planets until it passes Mars about four hours later.

January 25: The crescent moon is at the border between Cetus and Pisces. The star below to its left is Diphda (in Cetus); Pegasus (note the large "square") is above and to its right.

January 27: Apogee moon (farthest from the earth) is in Pisces.

January 28: First-quarter moon (at 10:29 P.M., EST) is in Aries. The star above it is Hamal, the brightest in Aries.

January 30: The gibbous moon is between the Pleiades (to the right) and Aldebaran (the reddish star to the left), all in Taurus.

January 31: We won't notice it, but Mercury passes Jupiter (a conjunction) today. Both morning stars rise too late in the dawn to be visible. The evening moon is above Aldebaran. Look along the right side of the V of stars (the Hyades), which includes Aldebaran at its tip, past the moon to El Nath, the star marking the Bull's left horn.

The winter Sky Map shows the sky for the months of January, February, and March, as viewed from latitude 40° north at the evening hours given below. To use the map, hold it vertically in front of you with north (N) at the bottom and match the lower half of the map with the stars you see when you face north. As you turn in other directions roll the map to bring the compass direction you face to the bottom of the map.

The stars move west slowly during the night. By morning (before dawn), stars on the western half of this map will have set, those on the eastern half will be in the west, and new stars (those of the spring evenings) will have risen in the east. The map represents the sky at about 2:00 A.M. on January 1; 1:00 A.M. on January 15; midnight on January 31; 11:00 P.M. on February 15; 10:00 P.M. on February 29; 9:00 P.M. on March 15; and 8:00 P.M. on March 31. The map can be used for an hour or more before and after the times given.

50% OFF NORMAL RETAIL

Merino Wool Mattress Pad

MANUFACTURER DIRECT

A tradition in Europe is sweeping America. Soft 100% Merino Wool cushions and cradles your body for a deeper, more restful night's sleep. Even the best mattress creates pressure points on the shoulders, hips and back. Soft, thick Merino Wool conforms to the contours of your body, relieving pressure points. Many people report they fall asleep faster, enjoy a more restful sleep and wake up feeling completely refreshed.

Wool is a natural insulator. In winter the pad retains body heat to keep you warm. In the summer, the pad keeps you cool by absorbing moisture.

The Wool Bureau has given this product the Superwash® designation. It can be machine washed and retain its original softness, resiliency and durability.

We use Merino Wool, absolutely the finest wool money can buy. Finally, we manufacture the pad ourselves and sell it directly to you, eliminating the middleman and retail markup and eliminating half the cost.

If you don't enjoy the best night's sleep you've ever had, simply return it to us for a complete refund. Delivery: Immediate.

Call toll-free 1-800-356-9367, Ext. R737, or write for your free catalog which includes 14 down comforter designs, premier quality down products and other bedroom accessories from America's Sleep Professionals.

The Comet That Woul

A satellite telescope has found a strange object that may be the long-sought missing link between comets and earth-crossing aste

by Stephen P. Maran

As the famed Halley's comet approaches, to appear in the sky in autumn of this year and the spring of 1986, the accompanying hoopla might easily obscure the fact that a number of other comets, many of comparable scientific importance, are also under study. On the first of January, Halley was still almost 404 million miles from the earth, a long way from its projected position in March 1986, when a fleet of European, Soviet, and Japanese spacecraft will sweep past it, taking photographs, spectra, and measurements, and when U.S. astronauts will pilot a space shuttle payload of powerful telescopes to observe it from the earth's orbit.

Meanwhile, other comets and related objects are undergoing concentrated study. One notable example is Comet Giacobini-Zinner, which on September 11, 1985, will be intercepted by NASA's International Cometary Explorer (ICE) space probe. Another is a recently discovered object called 1983 TB, which, although classified as an asteroid, follows the path of the Geminid meteoroid stream (the tiny objects that produce the Geminid meteor shower on Earth each December) and is almost surely a dead comet.

To brush up on nomenclature, a comet is a celestial body consisting of a solid nucleus (a few miles or less in diameter) that, as it approaches the sun, develops a surrounding atmosphere (the coma, tens to hundreds of thousands of miles across), and one or more tails. The tails may extend for a hundred million miles or more. A meteoroid is a rock or dust particle outside the earth's atmosphere in interplanetary space. Falling through the earth's atmosphere, a meteoroid is heated by friction that makes adjacent air molecules glow, producing the short-lived streak of light called a meteor, or "shooting st meteoroid that lands on the earth face is called a meteorite. A large n of meteors seen during a short tim (from hours to days) and all arrivin nearly the same direction is know meteor shower. (The most pron showers are the Perseids, which a about August 12 every year, an Geminids, which occur about Dec 14.) The huge collection of meteoro biting the sun, which produce a giv teor shower, is called a meteoroid s

Meteorites are chunks of rock an but they don't seem to come from m oid streams. Instead, they are appa fragments of asteroids, the solid that range from big rocks to tiny p and are confined mainly to the as belt between the orbits of Mars and ter. Asteroids differ from comets i they lack atmospheres and tails meteoroids involved in meteor show *not* chunks of rock; they appear to b fluffy dust particles. Some have ac been captured by U-2s and other su equipped, high-altitude jet aircraft ther, these meteoroids seem to com comets. The nucleus of a comet, acc to the famous dirty iceball theory, c of water ice and various frozen gas terspersed with dust particles. As t zen material at the surface of a com cleus evaporates under heating by t and turns into gas, the outward-stre gases blow the dust previously trap the ice back from the head of the co the direction opposite the sun, th forming a dust tail. All of the matter dust tail is subsequently lost to the forever as the tail streams backward the head. The lost dust gradually fi space around the comet's orbit in a

embles a stretched-out doughnut
because most comet orbits are
longated ellipses).
the earth, traveling its own
circular orbit around the sun,
through the stretched-out dust
ut of a comet, the dust particles
wn through the earth's atmo-
producing a meteor shower. There
ubt that this explanation of meteor
is correct, because there are clear
ions between the orbits of various
id streams and the orbits of cer-
nets. For example, there are two
meteor showers associated with
doughnut of Halley's comet, the
uarid meteors, which appear in
lay, and the Orionids, which ap-
out October 21.
the above, despite the confusing
logy (even comet and meteor ex-
suse some terms about as often as
them correctly) have made up a
nt story that is found in any num-
stronomy textbooks. The only fly
intment has been the case of the
ossing asteroids (often called the
and Amor asteroids). The sugges-
been made that they began their
comets rather than asteroids, even
as mentioned above, most evi-
dicates that comets and asteroids
lly different types of objects. Like
steroids, the Apollo and Amor
pear to be hunks of rock, but, as
rossing" implies, they are not con-
the asteroid belt as are the great
of known asteroids. Instead, they
h or even pass within the orbit of
h. Geophysicist George W. Weth-
ector of the Department of Terres-
agnetism at the Carnegie Institu-
Washington (D.C.), has main-

Why not switch to a Vanguard IRA?

HAVE YOU EARNED 21.4%* ANNUALLY ON YOUR IRA?

Vanguard's Windsor Fund has.

Consider the value of your IRA dollars had you invested in Windsor Fund. Annual contributions of $2,000 since 1982 ($6,000 total investment) invested in Windsor would have grown to $8,770.* That's an average annual return of 21.4%.

For the past decade, Windsor's proven long-term investment strategy has produced a total return of 754%, an average annual return of 23.9%!

Windsor Fund is one of 20 Vanguard Portfolios available for your IRA for as little as $500 (up to the $2,000 annual limit). And since there are no commission charges, all of your money goes to work for you immediately

So, before you make your next IRA contribution, consider what a Vanguard IRA has to offer: competitive performance and no commissions, plus the flexibility to exchange portfolios as your investment goals change with a simple toll-free call.

Call 1-800-662-SHIP

Ask for our free IRA Information Kit. Or send the coupon below.

In Philadelphia, visit our new Investment Center at 1528 Walnut St.

*As of September 30, 1984, all dividends and capital gains reinvested. Past performance is no guarantee of future rewards.

tained for years that the earth-crossing asteroids are not visitors from the asteroid belt but comets that have somehow lost their vital powers and can no longer produce a coma or a tail. This theory attracted much favorable attention in the past, although none from me. As an ardent believer in the dirty iceball theory of comets, I found it hard to imagine an iceball turning into rock. Sketches in some astronomy books do depict a big rock, beneath all the ice, at the center of a comet's nucleus, but there has been no direct evidence that such rocky cores actually exist. My concept of the death of a comet has always been that repeated bouts of solar heating, as a comet makes numerous orbital passes around the sun, turn the dirty ice into outflowing gas and dust and gradually lead to the comet's complete dissolution.

There are some meteor showers for which the parent comets have not been identified. Such was the case, until very recently, of the Geminid meteors. As recently as February 1983, three British meteor experts at Queen Mary College in London and the University of Sheffield commented that the parent comet of this meteor shower "has not been detected and . . . . probably completely decayed a long time ago." Thus, they seemed to share my feeling that comets are gradually reduced to nothingness. However, by December 1983, when the article in which this comment appeared was actually published, those three British scientists had made an important addendum: they noted that the parent comet had apparently been found, in the form of object 1983 TB.

Comets are usually named for their discoverers. Comet Kohoutek was named for Lubos Kohoutek, the Czech astronomer who found it, and Comet IRAS-Araki-Alcock (see "Thereby Hangs a Tail," *Natural History*, June 1984) was named for the Infrared Astronomy Satellite (IRAS), which discovered it, along with codiscoverers Araki and Alcock, in Japan and England, respectively. A famous exception to the rule is Halley's comet, named not for its discoverer (no one knows who that was) but for the English astronomer who first predicted in the early eighteenth century that the comet would return. When an asteroid is discovered, it is given a temporary designation consisting of the year of the discovery and some letters. Eventually, an international commission will name the asteroid, usually after anything or anyone but the discoverer. Thus, when IRAS found a previously unknown earth-crossing asteroid in November 1983, it was named 1983 TB.

Soon after its discovery, observations of 1983 TB made with ground-based telescopes at California, Hawaii, and elsewhere showed that it lacked any hint of an atmosphere or a tail, confirming that it should be classified and named as an asteroid. However, the computed orbit of 1983 TB is almost the same as that of the Geminid meteoroid stream, and since we know that meteoroid streams consist of dust from comets and cause meteor showers, there is a good possibility that 1983 TB is the long-sought parent comet of the Geminid meteors. Somehow, as Wetherill, the Carnegie geophysicist, had long maintained, an icy and dusty comet seems to have been transformed into a presumably rocky asteroid, lacking both an atmosphere and a tail.

The orbits of 1983 TB and the Geminid meteoroid stream are so nearly alike that almost any astronomer would be convinced of a causal association between the asteroid and the meteoroids. And 1983 TB has other unique properties that tend to support its identification as the missing link between comets and earth-crossing asteroids. For example, as an asteroid (so classified because of its lack of atmosphere and tail), 1983 TB comes closer to the sun than any other known asteroid, while as an inactive comet (producing no outpouring of gas and dust), it has the smallest orbit of any known comet.

I should mention that there have been previous accounts of purported missing links between comets and earth-crossing asteroids and between asteroids and meteoroid streams. However, the earlier evidence has never been persuasive.

Personally, I am convinced from its orbital characteristics that 1983 TB is the asteroidal or asteroidlike remains of the comet that produced the Geminid meteor shower, but as of this writing (October 1984), no solid supporting evidence for that belief has been cited. Asteroid and comet investigators Anita L. Cochran and Edwin S. Barker, of the University of Texas in Austin, obtained spectrograms of 1983 TB with the 107-inch telescope at McDonald Observatory near Fort Davis, Texas, and found no trace of emission from cometary gases. Photographs made at Palomar Observatory in southern California show no hint of a coma or tail. Infrared measurements made with NASA's 120-inch Infrared Telescope Facility on Mauna Kea, Hawaii, by Glenn Veeder of the Jet Propulsion Laboratory, have been combined with other data to determine the diameter of 1983 TB. Veeder reports that the diameter is about three to four miles, comparable to the size of most earth-crossing asteroids but large compared to the estimated diameters of the nuclei of most observed comets.

Lacking supporting evidence fo identification of 1983 TB as an old tive comet, we have to ask if there way, consistent with the known facts it could be just a plain asteroid. O swer is as follows: Although all mete streams are thought to be debris comets, a possible collision betwee asteroids might produce a sufficient ber of small particles of debris to cr phenomenon resembling a mete stream. Such a collision would be time event, so the stream would not long as the debris shed by a comet, persists for hundreds of thousands o millions of years, as the comet keeps ding each time it passes the sun. Re sightings of the Geminid meteor s have only been reported since 18 contrast to other meteor showers see ularly since antiquity. Further, cou the occurrence rates of the Geminid ors show that there are strong variati the number of meteoroids withi Geminid stream's orbit. This suggest the meteoroids have been shed by th ent object, 1983 TB, in the relative cent past and are not debris that acc lated over the millennia. These two may be consistent with the putative of the meteoroids in a collision be 1983 TB and another asteroid, but are probably good counterargument balance, since other meteoroid st are definitely associated with comet none are associated with other aste the case that TB is a dead comet is ger than that the Geminid meteoroi debris from an asteroid.

Short of visiting and inspecting 1983 TB, the best way to verify th clusion that comets evolve into crossing asteroids would be to id other likely examples of such an evol Astronomers are earnestly pursuin line of investigation. In fact, the word on the earth-crossing aste Oljato suggests that it too may be an tive comet. Lucy McFadden, an inve tor of asteroids at the University of land in College Park, reported October 1984 meeting of planetolog Honolulu that Oljato reflects sunligh "distinctly non-asteroidal" manne that it reflects radar transmissions the earth in a way suggestive of "a v regular, if not grotesque shape." that be the shape of a comet nucleu has lost its surface deposits of ice? also seems to interfere with the solar in a manner suggesting that unseen d similar to the debris in a comet tail, behind it.

Studies of 1983 TB and other crossing asteroids are of special in

space probes will probably begin
hese objects in the not too distant

Don't Buy a Big Tiller...

For A Small Job!

Don't let its small size fool you!

Buy a Mantis!

If your garden is an acre or more you may want to buy a big tiller. If it's any less you should buy a Mantis-20 (and hire somebody to plow or till your garden *once a year).*

Big tillers weigh almost 300 lbs. The Mantis weighs just 20 lbs. (women and older gardeners love it)!

Simply turning a 300 lb. tiller in a backyard garden without running over crops (or yourself) is a challenge. Mantis, on the other hand, starts with a flick of the wrist...turns on a dime...and weeds in and around plants, between narrow rows and along fence lines.

Most big tillers were designed to just till (although many now offer clumsy "add-on" attachments to try to justify their high cost). The Mantis-20 was designed *from the beginning* to precisely match a small, powerful engine to a variety of useful attachments for your yard and garden. Tiller. Cultivator. Furrower. Edger. Lawn Aerator. Lawn De-Thatcher. Hedge Trimmer. Despite the fact that the Mantis-20 is a tough, durable, precision instrument... it costs a *fraction* of what you'll pay for a big tiller.

3-Week In-Your-Garden Trial!

Finally, look at the warranty. Most machines are *partially* covered for 90 days to a year. The Mantis has a *Lifetime Warranty* on the tines (if they ever *break,* we'll replace them). A *Lifetime Replacement* agreement on the engine. And, best of all, a *3-Week In-Your-Garden Trial* (if you don't like it we'll take it back and give you a full refund!)

We have a 30' x 100' garden that is fenced to keep woodchucks out. We own a Troy-Bilt and had to take the fence down each time we wanted to till. Not any more! With our Mantis, we get in and out easily. My wife and I both think it's a great little machine!"

A Delectable Drupe

Both political upheaval and tax breaks have influenced the success of the American pistachio nut

by Raymond Sokolov

Somebody must have forgotten about Steven K., for that exuberant tyke rampaged without supervision in our basement rec room one afternoon in the fifties, spreading expensive pistachios and red-stained finger marks everywhere. He had been driven into a frenzy by his inability to open most of the nuts. Cleaning up after him was a major job, but I can now look back benignly on the chaos he caused because it is unlikely to be repeated. These days red-dyed pistachios are scarcer, the price of all pistachios is falling, and their shells are easier to open, less frustrating to tots and grown-ups alike.

Probably no foodstuff has gone through more thoroughgoing change in the last decade. Events and influences as widely scattered as the fall of the shah of Iran and the installation of an aqueduct in California have turned the exotic pistachio nut into a booming American crop, perfected botanically, harvested by the latest techniques, and launched by a tax loophole.

The pistachio began as a wild tree, probably in Asia Minor, where Neolithic peoples latched on to its grapelike clusters of red-hulled fruit and learned to like the meat they found inside the hard ivory kernels. Carbonized nuts from Stone Age settlements excavated in Jordan and Turkey have been dated to about 7000 B.C. Between that time and the 1970s, people spread *Pistacia vera*, a smallish, twenty-five- to thirty-foot deciduous tree, around the Mediterranean. Iran became the world's pistachio leader, with production centered in the Kerman region, also known for its rugs.

For the pistachio, botany was destiny. Like the peach, the pistachio is a drupe; its hull surrounds a hard-shelled kernel, with a crunchy, oily green or yellow "nut" inside. In fact, the pistachio is a memb
the same family, Anacardiaceae,
two other drupes of great economic i
tance, the mango and the cashew. T

ALASKAN WILDLIFE ADVENTURE

June 28—July 15, 1985

Join Kenneth A. Chambers, Lecturer in Zoology at the American Museum, for a journey to America's last great frontier. Cruise through fabulous Glacier Bay with its whales, seals and teeming birdlife. Explore scenic Denali (Mt. McKinley) National Park and see giant moose, white mountain sheep, barren ground caribou, and golden eagles. Visit volcanic Katmai and watch brown bears fishing for salmon.

Fly to the remote Pribilof Islands, summer home to over a million fur seals and countless, rare nesting sea birds. Limited to 25 participants. For further information write to DISCOVERY TOURS, American Museum of Natural History, CPW at 79th St. NY, NY 10024, or call (212) 873-1440.

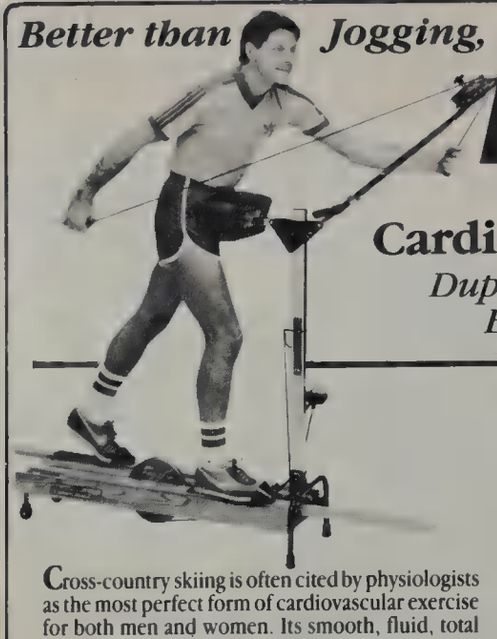
Discovery Tours

Better than Jogging, Swimming, or Cycling...



NordicTrack

Jarless Total Body

Cardiovascular Exerciser

Duplicates X-C Skiing for the Best Motion in Fitness

Cross-country skiing is often cited by physiologists as the most perfect form of cardiovascular exercise for both men and women. Its smooth, fluid, total body motion uniformly exercises more muscles so higher heart rates seem easier to attain than when jogging or cycling. NordicTrack closely simulates the pleasant X-C skiing motion and provides the same cardiovascular endurance-building benefits–right in the convenience of your home, year 'round. Eliminates the usual barriers of time, weather, chance of injury, etc. Also highly effective for weight control.

More Complete Than Running

NordicTrack gives you a more complete work out–conditions both upper body and lower body muscles at the same time. Fluid, jarless motion does not cause joint or back problems.

More Effective Than Exercise Bikes

NordicTrack's stand-up skiing motion more uniformly exercises the large leg muscles and also adds important upper body exercise. Higher pulse rates, necessary for building fitness, seem easier to attain because the work is shared by more muscle mass.

Even Better Than Swimming

NordicTrack more effectively exercises the largest muscles in the body, those located in the legs and buttocks. When swimming, the body is supported by the water, thus preventing these muscles from being effectively exercised. The stand up exercising position on the NordicTrack much more effectively exercises these muscles.

A Proven, High Quality Durable Product

NordicTrack is in its 7th year of production. NordicTrack is quiet, motorless and has separately adjustable arm and leg resistances. We manufacture and sell direct. Two year warrantee, 30 day trial period with return privilege.

Folds and stands on end to require only 15" x 17" storage space.

Mr. Zaloom anticipates that the g
in the San Joaquin and Sacramento
leys will harvest 40 to 50 million pou
nuts this year. He remembers the
when America grew only 1.5 m
pounds, and he is not timid about pr
ing that when the trees planted in Ca
nia in the 1970s come into full matur
the 1990s, the domestic crop will su
100 million pounds.

The California pistachio boom
major push when the Internal Rev
Service allowed Americans to inve
tax-sheltered pistachio orchards. Bui
on this "seed money," growers applie
vanced plant science and mechanica
vesting to their new trees. In Californ
vera is typically grafted onto hardier
stocks from other members of the
chio genus. Systematic pruning and
tegic placement of the pollinating
"Peters" variety (one for each eight
female "Kermans") have helped esta
flourishing, efficient groves.

Conventional soft-fruit type harve
equipment collects nuts from two tre
minute, shaking the nuts loose, cle
them, removing leaves and twigs.
men can harvest an acre in an hour

But the most dramatic improve
mechanization brought to pistachio
essing is the ability to dry and hull th
within twenty-four hours of colle
which greatly reduces mottling o
shells. Most nuts are now hulled b
friction of rubberized belts running

any blemished nuts.

California pistachios are not only
tier than Iranian ones; they are also
ger. Iranians range from eighteen to
nuts per ounce. Californians run as
fourteen to the ounce. And many mo
split Iranian nuts reach market.

But do the Californian nuts tas
good?

"Considerable controversy exists
United States concerning the re
merits of home-grown, as opposed
ported, pistachios," writes Fre
Rosengarten, Jr., in *The Book of E*
Nuts. "The American importers o
nian and Turkish pistachios describ
California counterparts as beautifu
tasteless. The California producers,
other hand, claim their pistachios
about the same as the imported nu
are larger, fresher, and easier to ope

Mr. Rosengarten, an associate in
nomic botany at Harvard's Botanica

rom whose new book much of the pistachios in this article derive, t take a stand on this dispute. Mr. says he is buying far fewer Ira-ts than ever before. "The Ameri-nsumer prefers the California ne says. "The California pistachio ttractive nut, and the consumer is t discriminating about subtle dis-s in taste. The California nut does seem drier. The drying process is than sun drying. But it's a very difference."

e for myself, I bought two differ-nds of California pistachios, la-s such, in a supermarket. Unable to ranian pistachios at any Manhat-rmet food shop, I went to Atlantic in Brooklyn, the national center ect food imports from the Near t Sahadi's market, I obtained two f Iranian nuts, one unlabeled, the as Zenobia's Shah variety.

our kinds of nuts I tasted were un-ed and undyed. There were virtu-ally no unsplit nuts in the two vacuum-packed jars from California. There were a small but noticeable number of unsplit nuts from Iran. The Californias were slightly larger.

As to taste, the Zenobia Shahs stood out. They were faintly aromatic, more complex. The other three were all perfectly good nuts, however, and I ate them all, leaving a large pile of tan shells on my desk.

This was a highly informal test, of course, and it did not include Albert Zaloom's favorite kind of pistachio, the tough little nuts grown in Sicily and rarely exported. But I emerged from my pistachio feast feeling largely content with the first fruits of the California boom, glad that the price of pistachios is dropping rapidly, and completely unsated in my appetite for this delectable drupe.

Raymond Sokolov is a writer whose special interest is the history and preparation of food.

rrot Pudding with Cardamom and Pistachios (Gajar ki Kheer)

(adapted from *Classic Indian Cooking*, by Julie Sahni)

ups milk
ablespoons long-grain rice
ups firmly packed peeled and rated carrots (about 1 pound)
up sugar
ablespoons slivered blanched al-nonds
easpoon ground cardamom
easpoon rose water
up heavy cream
ablespoons chopped, blanched, un-alted pistachios

ing the milk to a boil in a heavy-bot-ned 3-quart pan. Add the rice and r for a few minutes to prevent its set-ng. Reduce heat to medium–low, d cook the milk at a bubbling boil for minutes. The rice will be thor-ghly cooked and the milk reduced half. Stir often to insure that no skin ms.

ld carrots and continue cooking, un-vered, for 15 minutes or until the rrots are cooked and most of the lk has been absorbed by the carrots. ir often to prevent burning. (The ntents of the pan should reduce to a ck, pulpy sauce.)

ld sugar and almonds and cook, stir-g constantly, until the pudding is ry thick and begins to stick to the ttom of the pan (about 10 minutes). rn off heat, and let the pudding cool room temperature.

ir in cardamom, rose water, and cream. Cover with plastic wrap and chill thoroughly. Check the consistency of the pudding before serving. It should be slightly thinner than American rice pudding, but not runny. If it looks very thick, add a little milk. Serve in individual dessert dishes, sprinkled with chopped pistachios.

Yield: Six to eight servings

Pistachio and Honey Candy, Peloponnese Style (Pasteli Me Fistikia)

(adapted from *The Food of Greece*, by Vilma Liacouras Chantiles)

1 pound fresh, unsalted pistachio nuts
1¼ cups sugar
1 cup honey
Butter or oil

1. Preheat oven to 250 degrees.
2. Peel and place pistachios on a baking sheet, then roast in the oven for 20 minutes. Remove from the oven and cut into quarters.
3. Meanwhile combine the sugar and honey with 1½ cups water in a heavy pan and stir over medium heat until dissolved. Lower the heat and boil to the very firm ball stage (250 to 256 degrees), toss in the pistachios, and stir. Then remove from the heat.
4. Butter or oil a marble slab, jelly roll pan, or any aluminum baking pan and quickly spread the candy over it, using a spatula or knife.
5. Allow to cool. Then cut into squares and store in covered containers.

Yield: Fifty one-inch squares

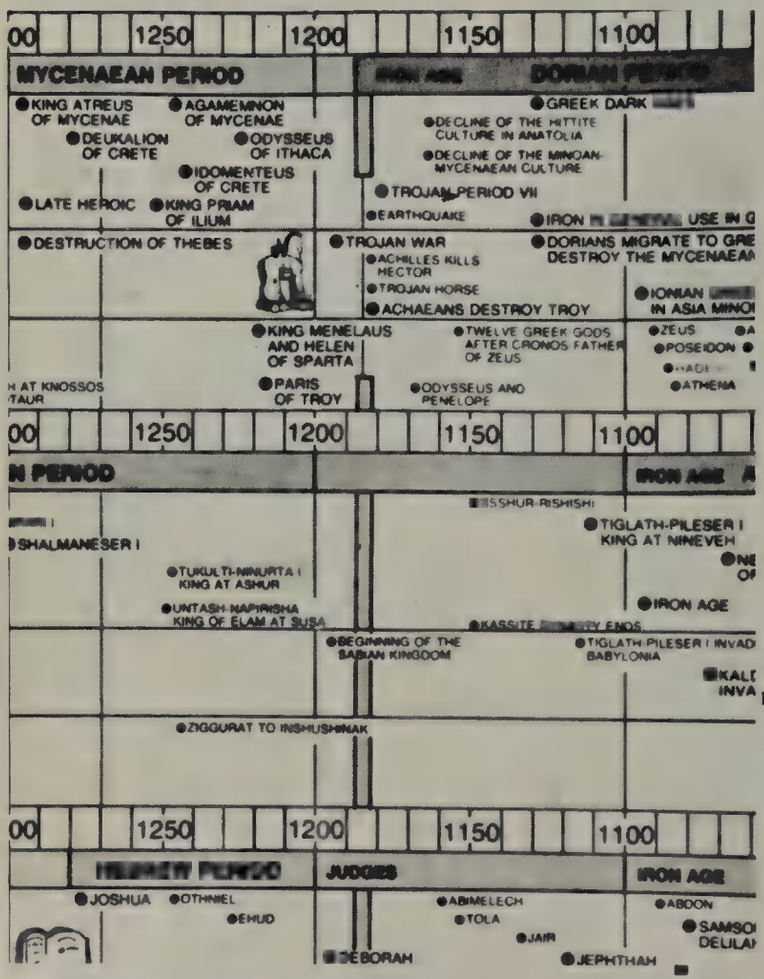
History comes alive. On The History Chart.



The history shown in this block is all contained in the small square indicated on the chart above.

If you think history is just a collection of dry facts, you should send for The History Chart today. Because The Histor Chart (34 inches high and 8 feel long!) is a fascinating 6000 ye chronology of the world's people and events to the present da understand the wealth of information contained in the Chart, history of the United States is only 2 inches old over 8 feet of

Just ask yourself the following questions. Who came fi the Romans or the Vikings? Did the Babylonian Captivity of Jews pre-date the Athenian Republic? Who brought the Greek gods to Egypt?

If you don't know (or even if you do), you'll find that Th History Chart is a uniquely enriching educational experience everyone. The History Chart has been on display in the Library of Congress.

There's no better way to see the panorama of human his archaeology, theology and mythology than The History Chart even includes suggestions for further reading.

So fill out the coupon (or write on a separate piece of pa and send it with your check or money order for $19.95 (plus $5 for shipping and handling) today. You'll soon be enjoying hist as you never have before.

Please send me The History Chart. Enclosed is my check or money order for $24.95 (which includes $5.00 for shipping and handling). Add $10 for laminated Chart.

The Long Goodbye

thia D'Vincent and her husband, Russ Nilson, saw this ack whale breaching near the tip of Admiralty Island in two summers ago. Cynthia, who reports that the whale to breach after a long feeding session with seven other wasn't sure what sent it skyward. "It could have been at, but we had been watching them all day," she says. "I t maybe it was trying to help itself digest its food."

do whales breach? To answer that question, *Natural* organized a symposium on breaching behavior in humphales and, to save everyone a lot of time and airfare, we no one. Instead, we talked to researchers from disparate f the United States and present here an edited transcript t was said.

.: Hello. Why do humpback whales hurl themselves headt of the water, then crash down to the surface?

VARD WINN (University of Rhode Island): Nobody really why they breach. A long time ago people thought they ying to get rid of parasites such as whale lice.

ER TYACK (Woods Hole Oceanographic Institute): Well, o lose a large mass of skin when they breach.

N: They may be responding to excitement or it may serve ggressive display, to drive another whale out of a territory.

.: You mean on the breeding ground?

N: That would be one instance. They also breach when is rough.

DALE RICE (National Marine Mammal Laboratory, Seattle): I think the excitement idea corresponds to what I've seen. They breach on the breeding grounds and on the feeding grounds in summer, and it looks to me like they're just having fun. Sometimes they slap a flipper down and you can hear it a mile away.

C. SCOTT BAKER (University of Hawaii): I've seen three basic types of situations in which breaching occurs. Calves breach all the time and this is probably just play, like frolicking in lots of mammals. When whales are under stress of any kind or are disturbed by humans—say by research boats—they'll breach more often. Finally, I've seen it in social encounters. When whales affiliate or disaffiliate, you may see breaching. Don't forget, though, that while a breach is spectacular to us, it's probably lost on every other whale in the vicinity. The main thing is the noise. Sometimes it may be a warning noise that says, "This is how big and excited I am."

TYACK: But they do have better ways of producing sound. Their song, for example, is acoustically higher than the noise of a breach. But the breach may be a more dramatic sound.

N.H.: Mr. Baker, could you elaborate on your reference to affiliation and disaffiliation?

BAKER: Well, sometimes when pods of whales come together, you'll see a few breach as they're coming together. Or if two whales are splitting up, they may both breach as they swim off.

N.H.: Both of them? You mean as if they're saying goodbye?

BAKER: Well, something like that.—*D.W.* ▶

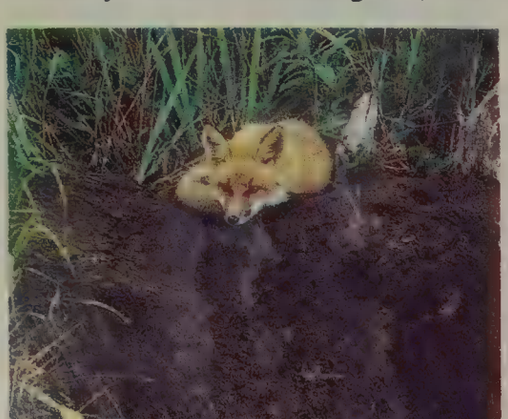
Additional Reading

Bald Ibis (p. 38)

Endangered Birds, edited by S. Temple (Madison: University of Wisconsin Press, 1978), is a collection of articles from the Symposium on Managing Techniques for Preserving Endangered Birds. It reviews the current methods used to save bird species in trouble, some of which go far beyond the old techniques for helping wildlife (such as legal protection and habitat preservation) to specific and intensive intervention into a species' life history and ecology. For example, to prevent the extinction of a small population of waldrapps (bald ibises' closest relatives) in Turkey, ornithologist U. Hirsch took some unusual steps, using highly untraditional methods. He widened the birds' breeding ledges and built additional ones; he prevented rubbish from being thrown from above and protected the site from other human disturbances; he identified the birds' preferred feeding areas and studied the effects of insecticides; and he tried to revive the local people's traditional ibis celebrations to engender concern for the birds' welfare. The bald ibis is now considered endangered by many ornithologists. G. Archibald et al. discuss the bird's status and its chances of survival in "Endangered Ibises (Threskiornithidae): Their Future in the Wild and in Captivity," which appeared in the *1980 International Zoo Yearbook* (pp. 6–17), an annual publication of the Zoological Society of London. W.R. Siegfried's "The Status of the Bald Ibis of Southern Africa" (*Biological Conservation*, vol. 3, pp. 88–91, published by Elsevier Publishing Co., New York) summarizes the bird's population, distribution, and other general data. Published in 1971, it is now slightly out of date but still valid as a good starting point for those interested in the ibis. To understand the bald ibis of the Drakensberg escarpment and the timing of its breeding system, it is useful to know about the area's fire ecology. A recent book, *Ecological Effects of Fire in South African Ecosystems*, edited by P. de V. Booysen and N.M. Tainton (New York: Springer-Verlag, 1984), takes a wide-ranging look at this field, exploring grass-burning management techniques and other related topics.



R. McNeil; Bruce Coleman Inc.

Red Fox (p. 46)

According to J.D. Henry, the red fox has evolved to become a very catlike canid, particularly in the ways it hunts. Henry, who studied red foxes in northern Saskatchewan, discusses their predatory strategies and proposes a theory of convergent evolution between foxes and cats in his last article for *Natural History*, "Fox Hunting" (November 1980, pp.60–69). Henry is also working on a new book—due out from the Smithsonian Institution Press, Washington D.C., sometime this year—in which he expands on these ideas. Two other books devoted to this species in particular are H.G. Lloyd's *The Red Fox* (London: Batsford Limited, 1980, distributed in the U.S. by David and Charles, New York), which concentrates on foxes in Britain, and *The Red Fox: Symposium on Behaviour and Ecology* (The Hague: Junk, 1980, distributed in the U.S. by Kluwer Boston, Higham, MA), a collection of articles edited by E. Zimen. A more general work is *The Wild Canids: Their Systematics, Behavioral Ecology, and Evolution,* edited by M.W. Fox (New York: Van Nostrand Reinhold, 1975). This thorough review of canid biology includes studies of the red fox's behavior and ecology, its status in the United States, and its genetics and physiology. D.W. Macdonald has written a number of articles on red foxes, among them "Helpers in Fox Society" (*Nature,* vol. 282, pp. 69–71), which takes a look at these animals' social organization and ways of rearing their young. Macdonald is also the author of *Vulpina* (London: Collins, 197 charming children's book on red f that is both amusing and scientificall curate. M. Taketazu's *Fox Family* (York: John Weatherhill, Inc., 19 translated from the Japanese and ada for Western readers by R.L. Gag highly recommended for its excepti collection of photographs recording a in the life of the foxes of Hokkaido pan's northernmost island. Coyotes also members of the canid family and ilar to foxes in many ways; for compar see *Coyotes*, edited by M. Bekoff (York: Academic Press, 1978), whic cludes articles on biology, behavior, management. Bekoff and M.C. Well plore the coyote's behavioral adapta to different food supplies and its proaches to predation in "The Social I ogy of Coyotes" (*Scientific Amer* April 1980, pp. 130–48). P.D. Moehl looks at the altruistic behavior of anc of the fox's close relatives in "Ja Helper and Pup Survival" (*Nature,* 277, pp. 382–83).

Genetics and Trees (p. 58)

If you are interested in learning m about this topic, you will probably ha resort to technical journals, where m of the pertinent material is found. An the most directly related articles are " netic Differentiation among Gro Forms of Engelmann Spruce and Su pine Fir at Tree Line," by M.C. Grant J.B. Mitton (*Arctic and Alpine Resea* vol. 9, pp. 259–63); "Genetic Variati Space and Time in a Population of derosa Pine," by Y.B. Linhart et al *redity,* vol. 46, pp. 407–26); "Relation Between Heterozygosity for Enzyme and Variation of Morphological Cha ters in Natural Populations," by Mitton (*Nature,* vol. 273, pp. 661– and "Observations on the Ecology Evolution of Quaking Aspen, *Pop tremuloides* in the Colorado F Range," by Mitton and Grant (*Amer Journal of Botany,* vol. 67, pp. 1040– Easier to understand, although per not as closely connected to this issue's cle on trees and genetics, are *Land A the Trees*, by H. Zwinger and B. Wi

ork: Harper and Row, 1972), a

Authors

"I have been an avid birdwatcher since I was twelve and have particularly admired ibises for their graceful, curvaceous forms," writes **David E. Manry** (p. 38). In pursuit of his prime interest, Manry spent one summer doing research on the nesting habits of the American white ibis in east Texas and five years as an avian researcher in South Africa for the Percy FitzPatrick Institute of African Ornithology. Now a graduate student in environmental, populational, and organismic biology at the University of Colorado, he plans to investigate the reproductive biology and mating systems of three closely related species of ibises on the plains of Venezuela for his Ph.D. dissertation. "I'm especially interested in pair formation, duration of pair bonds, remating, intraspecific nest parasitism, promiscuity, and maternity/paternity exclusion studies," he says. Manry's research allows him to indulge in some of his favorite hobbies—hiking, photography, and travel.

In 1971, **J. David Henry** (p. 46) was in Prince Albert National Park, Saskatchewan, working on a black bear management project, but he kept getting distracted. Everywhere he turned he noticed red foxes, and the way they hunted and interacted with each other intrigued him. Henry found that if he was patient, he could watch these animals and piece together what their daily lives were like in the wild. In o words, he was hooked. And for the fourteen years, he has been feeding habit—conducting red fox stu mainly in northern Saskatche where he lives, but also as far nort the Arctic islands. Henry teaches at University of Regina and is presider the National and Provincial Parks A ciation in Canada.

Jeffry B. Mitton (p. 58) is beguiled by how organisms in natural populations differ genetically and how the differences affect their physiology, life span, and fecundity. He has examined genetic variety in many plants and animals that inhabit a wide range of environments. His attraction to this subject, however, did not begin with the spruces, firs, and pines, which he writes about in this issue of *Natural History*, but with three marine organisms: the blue mussel, the common killifish, and the American eel. Research on these animals took him from Florida to Nova Scotia, but that was just the beginning. After earning his doctorate in 1973 from the State University of New York at Stony Brook, Mitton spent a year as an NIH postdoctoral fellow at the University of California, Davis, studying ryegrass. In addition to trees, he does fieldwork on the tiger salamander in Colorado and the queen conch in the Caribbean. An associate professor of biology at the University of Colorado and secretary of the Society for the Study of Evolution, Mitton's favorite sport, understandably, is scuba diving.

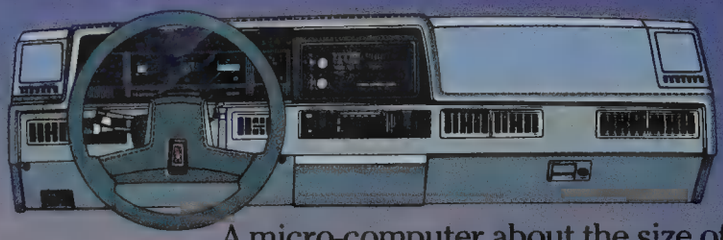
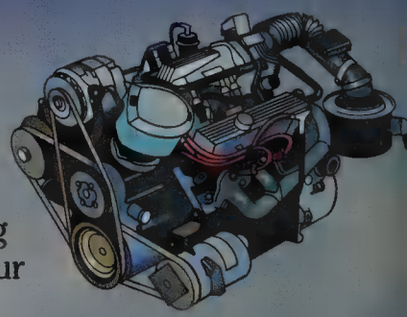
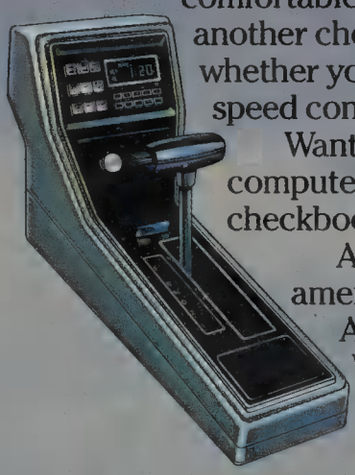
Olds Cutlass Ciera.
Computers helped design it.
Computers help you drive it.



Growing up in the computer age certainly has some attractive advantages. Just consider the 1985 Cutlass Ciera.



A micro-computer about the size of a deck of cards constantly tunes the engine as you drive, monitoring 20 vital engine functions. Another computer monitors temperature to keep you cool and comfortable when you order the available air conditioning. Still another checks the optional cruise control, ingeniously sensing whether you're going uphill or down, to automatically keep your speed constant.



Want to hear more? Then ask about the available auto calculator that can compute your mileage, estimate traveling time, even help balance your checkbook, with the push of a button.

And remember, above all Ciera is a Cutlass. The look is clean. The amenities—like the optional electronic instrument panel—are plentiful. And the power of the available 3.8 liter V6 with multi-port fuel injection? Well, you've got to experience it for yourself.

Olds Cutlass Ciera. Computers helped design it. For one good reason. So you can enjoy it. Test drive one today.

Oldsmobiles are equipped with engines produced at facilities operated by GM car groups, subsidiaries or affiliated companies worldwide.

The End of the Lines

Mass extinctions could change the course of evolution before the baby boom generation grows old

by Norman Myers

As many scientists and conservationists now know, we are on the verge of wave upon wave of extinctions. As is less commonly recognized, these extinctions may change the course of evolution. Human societies have long had an effect on the planet's biological systems, leading to the end of many species and occasionally to the formation of new ones. But unless we act superfast, this impending spasm of extinction will surely surpass all others in prehistory, in terms of the number of species involved and the speed with which it will happen. As in the past, new life forms will arise, but not at a fraction of the rate they are going to be lost in the coming decades and centuries. We are surely losing one or more species a day right now out of the five million (minimum figure) on Earth. By the time ecological equilibrium is restored, at least one-quarter of all species will probably have disappeared, possibly a third, and conceivably even more. With so many plants and animals gone, there will be a fundamental shift in evolution itself, as evolutionary processes go to work on a vastly reduced pool of species and as a few new species arise to fill in the gaps.

Of course, there have always been spasms of natural extinctions. The demise of the dinosaurs and their kin, together with numerous marine species, during the "great dying" 65 million years ago, eliminated between one-third and one-half of all animal and plant groups (although there were rather fewer species overall in those far-back times than today). There was an even greater megaextinction, during the late Permian 230 million years ago, when possibly three-quarters of all species were lost, out of a much smaller total than exists today.

But whereas the extinctions of the Permian, and of five other major episodes in the prehistoric past, appear to have extended over several million years at least, the current catastrophe has begun in the last few decades and is likely to do much of its damage by the middle of the coming century. Particularly since World War II, tropical forests, which cover only 7 percent of the earth's surface, have been under assault in Latin America, tropical Africa, and in Asia. These forests, which support about half of all species, are being cleared for agriculture and logged at an enormous rate. A third of them are already gone. Ecuador has lost half its forests, and in Madagascar, which has a quarter of a million species, two-thirds of which occur nowhere else, 90 percent of the forests have been cut. This is the case for country after country. Seventy percent of these losses have been brought about by peasants who practice slash-and-burn agriculture and have had to roam farther and farther into the forests to grow subsistence crops. Another 15 percent of the loss is due to cattle ranching in Latin America—the so-called hamburger connection in which large fast-food outlets in the United States and Europe foster the clearance of forests to produce cheap beef. And 15 percent of the forests have been cut for lumber. If this pattern continues, it could mean the demise of two million species by the middle of the next century.

Two other crucial ecosystems that have suffered terribly in recent decades are wetlands and coral reefs. Coral reefs, for example, cover about 220,000 square miles of the ocean floor in the Indian Ocean and the western Pacific, among other areas, and support about 200,000 species. During the past fifty years, countries such as the Philippines, Kenya, and Tanzania have dredged reefs in the
ters, and sometimes dynamited the
make shipping lanes. Coral reefs ar
verted in some countries into a subs
for concrete. The number of spec
stake is obviously far smaller in thes
systems than in tropical forests, bu
are no less important. Coral reefs,
lands, and estuaries all have an e
tional abundance and diversity of s
and are unusually complex in thei
logical workings. Moreover, since
environments, along with tropical fo
are the preeminent "powerhouses" o

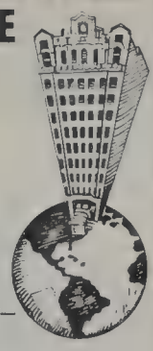
THERE IS NO OTHER STORE IN THE WORLD LIKE HAMMACHER SCHLEMMER. AND NO OTHER CATALOG.



It has been said, "If you can't find it anywhere else look for it at Hammacher Schlemmer—especially if it's new."

For well over a century New Yorkers and ex-New Yorkers around the world have looked to Hammacher Schlemmer for things ahead of their time—the first portable radio, the first automatic coffee maker, the first microwave oven—and hundreds of other products before anyone else had them.

In our new catalog you'll find the Electronic Credit Card Alarm Wallet, the Remote Control Car Starter, the Swiss Tailor's Press and still hundreds more of unusual things that can't be found elsewhere. Come to the famous store on 57th Street or send for the current catalog while it's still available.

Hammacher Schlemmer, Dept. 808

will be the hiatus in evolutionary processes that they will cause. And we are being optimistic when we call it a hiatus. A more likely outcome is that many evolutionary developments that have taken place since the first flickerings of life will be suspended or even terminated.

The forces of natural selection can work only with the resource base they have. If that base is drastically reduced, the result could be a disruption that could persist far into the future. So far as we can discern from the geologic record, the "bounce-back" time may require several million years. Following the crash during the late Permian, for example, when the marine invertebrates lost about half their families, it took 20 million years before the survivors could establish even half as many families as they had lost.

In short, as M.E. Soule and Bruce A. Wilcox have written, "Death is one thing; an end to birth is something else."

Even as this megaextinction episode is taking place, some of the same disruptive processes causing it could lead to an outburst of speciation—the formation of new species. We can consider several categories of disruption. When species' populations are cut off from one another, which occurs when humans destroy swathes of habitat through the middle of a species' range, each population develops in its own way. Such a population eventually becomes distinct enough from the others that it can no longer interbreed with them, whereupon it ranks as a new species.

We can discern the results of this when we consider the great lakes of East Africa. In Lake Tanganyika there are 134 cichlid fish species that are endemic, that is, found nowhere else, while in neighboring Lake Malawi there are about 200 such species. Although the two lakes are no more than 200 miles apart (they were once one big lake), they possess not a single cichlid in common. At some point in the past, an ancestral species living as a single population began to split up into smaller populations, probably because of small changes in the shoreline that cut some fish off from others. Over the course of millions of years, the microhabitats of each of these populations led to the formation of hundreds of new species. In a small "offshoot" of Lake Victoria, known as Lake Nabugabo, which only 4,000 years ago was separated from its parent lake by a sandstrip that is now less than two miles wide, there are six species of *Haplochromis*, five of them endemic. These have to rank among the "youngest" fish species known. Under natural conditions, then, fish can radiate, or throw off new species, in relatively short periods.

A second sort of disruption th
greatly accelerate natural evolu
processes is the introduction of
sources or other materials into a
environment. In Hawaii, for ex
there were no bananas until human
duced them about 1,000 years ag
which several moth species of the
Hydylepta emerged. The interestin
about these new moths is that th
exclusively on banana plants; oth
cies of the genus feed on grasses,
lilies, palms, and legumes.

In just the past few decades mo

Spend sixty minutes with

David Attenborough in The Living Planet: A Portrait of the Earth

A spaceman landing on Planet Earth would discover that various parts of this uniquely rich world, even though they are widely separated in space are, nonetheless, remarkably similar. The Sahara in the northern half of Africa, the southern part of North America and the centre of Australia are very like one another—bakingly hot and starved of water. They are deserts. And, amazingly, although the animals and plants that live in these deserts come from different ancestral stocks, they nonetheless resemble one another to a surprising degree, moulded by similar conditions to develop similar techniques for solving similar problems of survival.

If that spaceman then travelled round the equator from South America to Borneo to West Africa, he would find, once again, extraordinary similarities—lush forests nearly two hundred feet high, swarming with more animals and plants than you could find in any other kind of country, different in details yet again and again paralleling one another.

This series follows the travels of such a spaceman. One by one, we visit the great environmental regions of the world to examine the ways in which animals and plants, over the millennia, have managed to colonise not only the most fertile and favoured parts of Planet Earth, but even the most hostile. By the time we have finished our tour, we will have scanned the entire globe from the Poles to the equator, from the depths of the ocean to the outer limits of the atmosphere. By discovering the ways in which living organisms have colonised these varying environments, we will begin to understand how they continue to exist. And by doing that we will be able to see more clearly not only what has to be done if we want to conserve them—but what marvels we will lose if we fail to do so.

David

A twelve-part series written and narrated by David Attenborough

converted into pastureland within a single season), the time required to produce a new species is much longer. It takes decades for outstandingly capable contenders such as certain insects; centuries, if not millennia, for many other invertebrates; and hundreds of thousands or even millions of years for most mammals.

The most important factor in encouraging speciation is that a broad-scale extinction of species will vacate many niches. This will allow new species to emerge more rapidly than when there are diverse and abundant numbers of species, as there are today. But we know too little about this process in principle, and it will take too long to reveal itself in practice, for us to make any prognostications right now.

What we can suppose with some confidence is that the reduced stock of species that survives the present burst of extinction will likely contain a disproportionate number of opportunistic, or "clever," species. Such species rapidly exploit newly vacant niches (by making widespread use of food resources), are usually short-lived (with brief gaps between generations), feature high rates of population increase, and are adaptable to a wide range of environments—all traits that enable them to exploit new environments and to make excellent use of "boom seasons." These are the attributes that enable opportunistic species to prosper in a human-disrupted world, where they often become pest amples include the English sparrow European starling, the housefly, the bit, and the rat, plus many "weed" p

But this trend toward opportunism ries with it a sizable cost. The sparro example, is adept at usurping the stocks and nesting sites of many n North American birds, notably bluel wrens, and swallows. Entire populati these species are being displaced and planted, leaving them with less prom prospects of survival. The same thi happening in other regions of the that the sparrow has colonized with help, especially South America, Sout rica, southeastern Australia, and Zealand.

A parallel situation has arisen in n western Europe. The herring gull's p lations in the North Atlantic are thirty times larger than at the beginni the century, mainly because of the ing amounts of domestic garbage, sew and fishing offal. As a result, several birds, notably the rarer terns, are suff through competition for nesting spa Britain, there are now only about 2,0 seate terns left, or one-quarter as ma in the mid-1960s. Both the sparrow the gull illustrate how the rise of o tunistic species can contribute furth the extinction pattern.

If generalist, or opportunistic, sp will profit from the coming crash, the cialists, notably predators and para will probably suffer disproportion high losses. This is because their life s are much more refined than the oppo ists'; and their numbers are gene much smaller anyway. Since the sp ists are often the creatures that keep the populations of opportunists, there be little to hold the pests in check. T probably less than 5 percent of all i species deserve to be called pests. E extinction patterns tend to favor c species, the upshot could soon be a s tion where these species increase their natural enemies can no longer trol them. In short, our descendants find themselves living in a world w "pest and weed" ecology.

Some observers may assert that ou works of parks and other protected will surely keep species alive, albeit remnant stocks of individuals. But the next several thousand years, eve best-protected areas will slowly lose of their species, as habitat destructi creasingly isolates them. Several r studies of species' distributions in p and other islands of wildlife provi with some insight into this process. established, a park is virtually certa

For the cost of a morning coffee break, you can break the cycle of poverty for one small child.

It may not seem as though 72¢ will go very far these days. But for a small child like this, it can lead her out of desperate poverty and into a future of hope.

And right now, you can reach out and make that future happen ... by sponsoring one child overseas through Foster Parents Plan. For only 72¢ a day, you can make it possible for your Foster Child and family to have adequate food and clothing, a decent place to live, needed medical care, education ... *and the chance for a better life.* Because while you're helping, the child's own family will be working with Foster Parents Plan to develop the skills and resources they need to help themselves.

You'll be amazed at the difference you can make. And you'll see the difference for yourself. In photographs. Detailed progress reports. And heartwarming letters from your Foster Child. You'll be doing so much for that child ... and for so little.

Won't you help now? Simply mail the coupon today or call toll-free. It could be the biggest break a child ever got.

Founded in 1937, Foster Parents Plan will this year bring its unique, person-to-person program and effective services to over 236,000 Foster Children and their families in more than 20 countries. We are non-profit, non-sectarian, non-political, and respect the culture and religion of the families we assist. A detailed annual report and financial statement are available on request. Your sponsorship is 100% tax-deductible.

To start helping even faster, call toll-free:

HIMALAYA

NEPAL FAMILY TREK

Daku Tenzing Norgay, wife of Everest summiteer Tenzing Norgay, will lead a group of families on a unique adventure in the Helambu region of Nepal. This charming Sherpa lady will guide us through several foothill villages introducing us to the differing cultures and fascinating traditions of the local people. Above are spectacular views of the Himalaya including the massive Annapurna Range to the west. There will also be time to explore the ancient cities of the Kathmandu Valley.

Since 1977, **HIMALAYA** has offered a wide range of walking trips focusing on the cultures of remote **Nepal, China/Tibet, Kashmir/ Ladakh, Bhutan, Sikkim,** and **Pakistan** as well as mountainous **Japan** and **New Zealand.**

For an illustrated travel portfolio detailing all of our trips, write or call HIMALAYA, INC., 1802 Cedar St. Berkeley, CA 94703, (415) 540-8031

become an island of intact nature in a sea of human-dominated, and hence alien, environments; and the species on that island will steadily decline in number, compared with what was living there when the area was part of a "continent": an island can support only so much life. Generally speaking, if 90 percent of an original habitat is grossly disrupted, and the remaining 10 percent is protected, we can expect to save no more than about half the species in that area.

This means that, in operational terms, a tropical park of, say, 4,000 square miles (larger than Yellowstone National Park, the largest park in the conterminous United States) could well lose about half of its large mammal species in a few thousand years—unless park managers master "constructive interference," that is, management to safeguard depleted gene pools (a challenge we are barely coming to grips with). It further means that if all that eventually remains of the tropical forests of, say, Amazonia amounts to the areas currently protected, we can expect, according to Daniel Simberloff of Florida State University, to lose roughly two-thirds of the region's half million (minimum figure) species within a few thousand years.

For sure, a few thousand years is a long time by some standards. But in the conservation perspective, it is the twinkling of an evolutionary eye. The spectacular throngs of East African savannas—the vast herds of elephants, giraffes, zebras, and antelopes, together with their lions and other predators—probably face the same deadline. Because we have established so few parks of suitable size, and because our options for establishing any new parks are rapidly running out, certain observers, such as Soule and Wilcox, believe that we could well lose many, if not most, of our large mammals and birds within another 5,000 years—"large" meaning anything heavier than a few pounds. If we use the crash at the end of the Cretaceous as a model, we can anticipate that the eventual mammal survivors of the imminent crisis will likely be small-sized creatures, such as bats, rodents, rabbits, small canids, weasels, and raccoons.

More important, a park-based strategy for protecting species would not help much in safeguarding the future course of evolution. Of course, were we to establish extensive networks of outsized parks, we could keep many more species alive. But this would certainly not assure the perpetuation of evolutionary processes as they operate today. Even fairly small mammals apparently need unexpectedly large areas if they are to retain their capacity to throw off new species. To
optimistically, we are probably for
ing the prospect that our decendant
ever see a distinctive variation of the
or the cheetah or any other large cat,
which require huge ranges to mainta
size of populations on which natural
tion can work.

All this raises questions virtual
large as conservationists can visu
Would we be content to hold on t

Paper/Office Products/Packaging/Building Products/Forests

Unfortunately we are "deciding" out even the most superficial reflect deciding all too unwittingly, yet tively and increasingly. The impe upheaval in evolution's course coul as one of the greatest biological r tions of paleontological time. It will in scale and significance the develo of aerobic respiration, the emerge flowering plants, and the arrival of li animals. But of course, the prosp degradation of many evolutionary c ties will be an impoverishing, not ative, phenomenon.

In short, the future of evolution s rank as one of the most challenging lems that humankind has ever en tered. After all, we are the first s ever to be able to look upon nature's and to decide whether we would re part of it—to consciously determin lution by what we do or don't do.

Fortunately there are signs—a glimmerings—of a new spirit eme The mass extinction of species is no seen as a preoccupation of cutesy-cr enthusiasts and ecofreaks. It is bein ceived as a vast rending of the fabric with pragmatic implications for ci around the world, now and for gener to come. In turn, the message is picked up by political leaders—mos by the government of the United S In 1981, the State Department con an international Strategy Conferen Biological Diversity (meaning biol depletion). And in 1983 Congress p the International Environment Prot Act, which requires the govern through its foreign aid programs, a other activities, to take special acco species communities and gene rese throughout the world.

By comparison with the needs situation, this can all be viewed as f little and far too late. But it is a st ward recognizing one of the great s issues of our time. The first great wa extinctions are only beginning to over the earth. We can still save spec the millions. Should we not conside selves fortunate that we alone amon erations are being given the chance t port the right to life of a large share fellow species and to safeguard th ative capacities of evolution itself?

Norman Myers is a journalist a environmental consultant to such nizations as the World Bank, the In tional Union for the Conservation ture, and the World Wildlife Fun won the Fund's Gold Medal in 19 his conservation work. His latest bo GAIA: An Atlas of Planet Manage

Nasty Little Facts

In science, one fact, like a single foot soldier, almost never decides a great battle

by Stephen Jay Gould

As a devotee of Grade B detective films, from Charlie Chan (in all his incarnations) to the *Thin Man*, I have, perforce, spent an undue amount of time passively engaged in conversations about fingerprints. Since these discussions are interminable, one might suspect that they have also been eternal in the annals of criminology.

In fact, Scotland Yard officially introduced fingerprints as a tool for identifying criminals in 1901 (replacing the older Bertillon system, based on complex series of body measurements and the accompanying assumption, not always vindicated, that no two people will be alike in so many ways). The chief architect and promoter of the new system was Francis Galton, England's most eccentric scientific genius.

In his autobiography, Galton tells a story of Herbert Spencer's visit to his fingerprint lab. Galton took Spencer's prints and "spoke of the failure to discover the origin of these patterns, and how the fingers of unborn children had been dissected to ascertain their earliest stages." Spencer, quick to offer certain opinions about almost anything, told Galton that he had been working the wrong way round.

> Spencer remarked . . . that I ought to consider the purpose the ridges had to fulfil, and to work backwards. Here, he said, it was obvious that the delicate mouths of the sudorific glands required the protection given to them by the ridges on either side of them, and therefrom he elaborated a consistent and ingenious hypothesis at great length. I replied that his arguments were beautiful and deserved to be true, but it happened that the mouths of the ducts did not run in the valleys between the crests, but along the crests of the ridges themselves.

Galton then ends his anecdote by giving the original source for one of the top ten among scientific quotes. Spencer, dining with T.H. Huxley one night at the Athenaeum, stated that he had once written a tragedy. Huxley replied that he knew all about it. Spencer rebutted Huxley, arguing that he had never mentioned it to anyone. But Huxley insisted that he knew anyway and identified Spencer's debacle—"a beautiful theory, killed by a nasty, ugly little fact."

Some theories may be subject to such instant, brutal, and unambiguous rejection. I stated last month, for example, that no left-coiling periwinkle had ever been found among millions of snails examined. If I happen to find one during my walk on Nopsca beach tomorrow morning, a century of well-nurtured negative evidence will collapse in an instant.

This Huxleyan vision of clean refutation buttresses one of our worst stereotypes about science. We tend to view science as a truth-seeking machine, driven by two forces that winnow error: the new discovery and the crucial experiment—prime generators of those nasty, ugly little facts. Science does, of course, seek truth; it even succeeds reasonably often, so far as we can tell. But science, like all of life, is filled with rich and complex ambiguity. The path to truth is rarely straight, marked by a gate of entry that sorts applicants by such relatively simple criteria as age and height. (When I was a kid, you could get into Yankee Stadium for half price if your head didn't reach a line prominently drawn on the entrance gate about four and a half feet above the ground. You could scrunch down, but they checked. One nasty, ugly day, I started to pay full price, and that was that.)

Little facts rarely undo big theories all by themselves—the myth of David and Goliath notwithstanding. They can refute little, highly specific theories, like my conjecture about lefty periwinkles, but they rarely slay grand and comprehensive views of nature. No single, pristine fact taught us that the earth revolves around the sun or that evolution produced the similarities among organisms. Overarching theories are much bigger than single facts, just as the army of Grenada really didn't have much chance against the combined forces of the United States (though you'd think from the consequent appeals to patriotism that some gigantic and improbable victory had been won).

Instead, little facts are assimilated into large theories. They may reside there uncomfortably, bothering the honorable proponents. Large numbers of little facts may eventually combine with other social and intellectual forces to topple a grand theory. The history of ideas is a play of complex human passions interacting with an external reality only slightly less intricate. We debase the richness of both nature and our own minds if we view the great pageant of our intellectual history as a compendium of new information leading from primal superstition to final exactitude. We know that the sun is hub to our little corner of the universe, and that ties of genealogy connect all living things on our planet, because these theories assemble and explain so much otherwise disparate and unrelated information—not because Galileo trained his telescope on the moons of Jupiter or because Darwin took a ride on a Galápagos tortoise.

This essay tells the story of a pristine, unexpected little fact that should have mattered, but didn't particularly. It was

The South Pacific for $949.

Enchanting tropical islands. Captivating New Zealand. And big, booming Australia.

Now you can get them all for just $949, from Los Angeles or San Francisco.

Qantas has a special offer that lets you visit your choice of four South Pacific destinations. The menu includes islands like Tahiti, Fiji and Hawaii. Australian cities like Sydney, Brisbane, and Cairns. And Auckland, Wellington, and Christchurch in New Zealand.

"This deal was perfect until they threw in Australia."

You can put together lots of different itineraries. You might visit Tahiti first, go on to Sydney, and stop at Fiji and Hawaii on your way home. Or go straight to Cairns (gateway to the Great Barrier Reef), then Auckland, and on to Sydney and Tahiti before flying back to the United States.

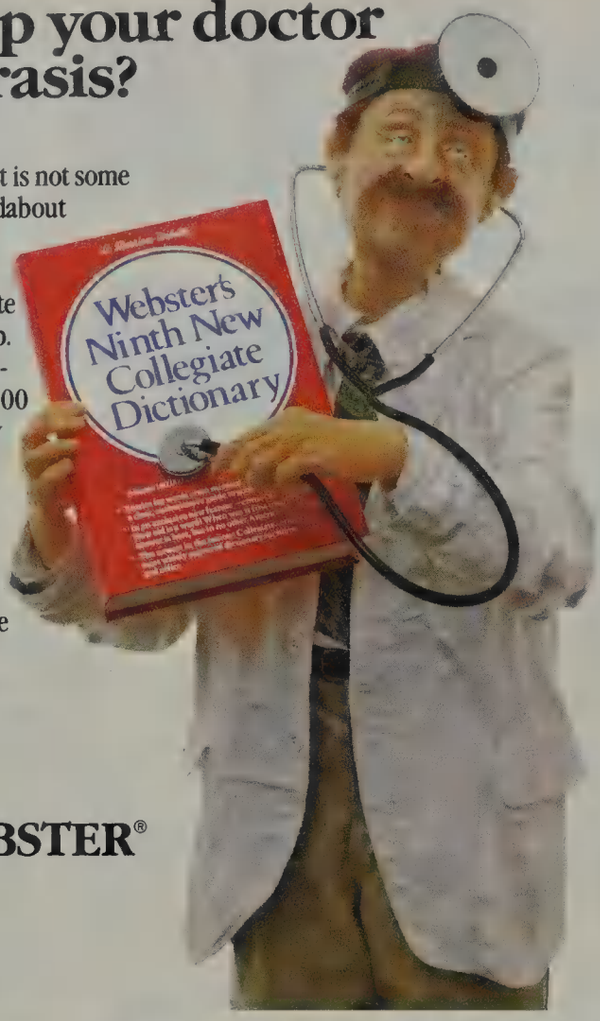
Not all combinations are possible. (You must visit at least one city in Australia, for example.) But you have enough choices to plan the South Pacific vacation you've always wanted. At the fare you've always hoped for.

For details and reservations, see your travel agent or call Qantas. Then get out a map, and start planning.

QANTAS

The $949 fare is available from April through November, but tickets must be purchased at least 21 days in advance of departure, and no later than March 31, 1985. Other special fares are available for travel in February and March. Fares subject to government approval and change without notice.

Who can help your doctor cure periphrasis?



Periphrasis may be a scourge but it is not some dread disease. It is the use of roundabout language instead of something shorter and more direct.

Webster's Ninth New Collegiate Dictionary, just published, can help. This new edition of America's best-selling dictionary has almost 160,000 entries including thousands of new ones, all defined clearly, concisely, and accurately. And at many of those problem words, you'll find authoritative essays on contemporary usage.

Webster's Ninth New Collegiate Dictionary. It's the one to turn to when you want to know about the language.

Take our word for it.

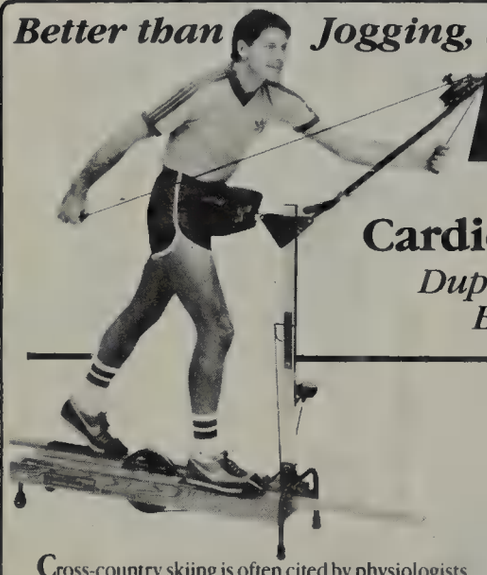
Better than Jogging, Swimming, or Cycling...



NordicTrack

Jarless Total Body

Cardiovascular Exerciser

Duplicates X-C Skiing for the Best Motion in Fitness

Cross-country skiing is often cited by physiologists as the most perfect form of cardiovascular exercise for both men and women. Its smooth, fluid, total body motion uniformly exercises more muscles so higher heart rates seem easier to attain than when jogging or cycling. NordicTrack closely simulates the pleasant X-C skiing motion and provides the same cardiovascular endurance-building benefits–right in the convenience of your home, year 'round. Eliminates the usual barriers of time, weather, chance of injury, etc. Also highly effective for weight control.

More Complete Than Running

NordicTrack gives you a more complete work out–conditions both upper body and lower body muscles at the same time. Fluid, jarless motion does not cause joint or back problems.

More Effective Than Exercise Bikes

NordicTrack's stand-up skiing motion more uniformly exercises the large leg muscles and also adds important upper body exercise. Higher pulse rates, necessary for building fitness, seem easier to attain because the work is shared by more muscle mass.

Even Better Than Swimming

NordicTrack more effectively exercises the largest muscles in the body, those located in the legs and buttocks. When swimming, the body is supported by the water, thus preventing these muscles from being effectively exercised. The stand up exercising position on the NordicTrack much more effectively exercises these muscles.

A Proven, High Quality Durable Product

NordicTrack is in its 7th year of production. NordicTrack is quiet, motorless and has separately adjustable arm and leg resistances. We manufacture and sell direct. Two year warrantee, 30 day trial period with return privilege.

Folds and stands on end to require only 15" x 17" storage space.

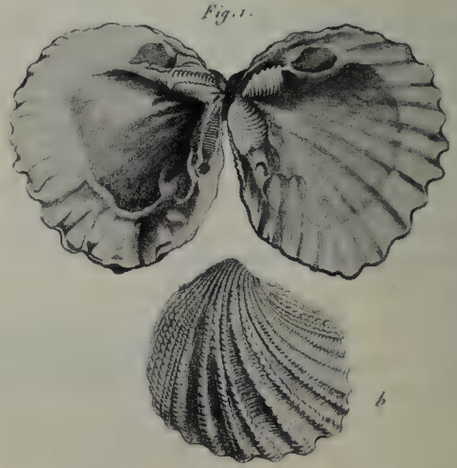
widely reported, discussed, and personally studied by the greatest naturalists of Europe, and then assimilated into each of several contradictory systems. Fifty years later, in 1865, a second discovery resolved the paradox generated by the first fact—and should have won, by Huxley's principle, a big and important victory for Darwin and evolution. It was welcomed, to be sure, but largely ignored. One foot soldier could not decide a battle waged on so many fronts.

Trigonia is a distinctive clam, thick shelled and triangular in shape. It flourished with dinosaurs during the Mesozoic era and then became extinct in the same debacle that wiped out the ruling reptiles—one of the five greatest mass dyings in our geologic record. No trigonian had ever been found in the overlying Cenozoic strata—the entire age of mammals (about sixty million years, as we now know). *Trigonia* had therefore become a valued "guide fossil"; when you found one, you knew you had rocks of the earth's middle age. Everyone (who was anybody) understood this.

Then, the nasty, ugly little—and quite undeniable—fact. In 1802, P. Péron, a French naturalist, found the shell of a living trigonian washed up on the beaches of southern Australia. Twenty-five years later, and following several failures, J. Quoy and J. Gaimard, naturalists aboard the *Astrolabe*, finally found a live trigonian. They had dredged for several days with definite purpose, but without success. Becalmed one night in Bass Strait and with little else to do, they tried again and brought up their single prize, a molluscan life soon snuffed and preserved in the (perhaps welcome) medium of the collector's trade—a bottle of alcohol. Quoy and Gaimard treasured their booty and wrote later:

We were so anxious to bring back this shell with its animal that when we were, for three days, stranded on the reefs of Tonga-Tabu,



Original figure of living trigonian by Lamarck (1804)

was the only object that we took from our llection. Doesn't this recall the ardent ell collector who, during seven years' war, rried constantly in his pocket an extraor-nary *Phasianella*, which he had bought twenty-five louis?

A simple story. A fact and a puzzle. *rigonia* had not disappeared in the great retaceous debacle, for it was hanging ugh in Australia. But no fossil trigonians d been found in all the strata in be-veen—throughout the long and well-re-rded history of the age of mammals ow called the Cenozoic era). Where ere they? Had they ever existed? Could ch a distinctive animal die and be re-rn (or re-created) later? The "Cenozoic p" became as puzzling and portentous the one later associated with Mr. Nixon d Ms. Woods.

Trigonia occupies a specially interest-g place in the history of biology because unexpected fact and consequent puzzle ose and prevailed at such an important me—at the dawn and through the great-t conceptual transition ever experienced the profession: from creationist to evo-tionary views of life. It also (or rather erefore) attracted the attention and mmentary of most leaders in nine-enth-century natural history. J.B. La-arck, most famous of pre-Darwinian olutionists, formally described the first ing trigonian. Darwin himself thought d commented about *Trigonia* for thirty ars. Louis Agassiz, most able and co-nt of Darwin's opponents, wrote the ma-r technical monograph of his generation the genus *Trigonia*.

The lesson of the living *Trigonia* can be stilled in a sentence: Everyone made the st of it, incorporating favorable aspects this new fact into his system and either noring or explaining away the difficul-es. *Trigonia* became an illustration for eryone, not a crucial test of rival theo-es. Evolutionists celebrated the differ-nces in form and distribution between an-ent and modern trigonians—and ig-ored the Cenozoic gap. Creationists ghlighted the gap and made light of the fferences.

Today, we remember Lamarck best as e author of a rejected evolutionary the-y based on the inheritance of acquired naracters (quite an unfair designation nce so-called Lamarckian inheritance epresents a minor part of Lamarck's own stem—this, however, is another story, r another time). But his day-to-day work post-revolutionary France involved the escription of living and fossil inverte-rates in his role as curator at the *Mu-eum d'Histoire Naturelle* in Paris. He herefore received Péron's precious shell

Exciting Breakthrough For Suburban Gardeners!

At last!

Now there's a tiller/cultivator exclusively designed for small backyard gardens.

No longer do you have to choose between a yank-you-along *front-tine tiller* and a clumsy, hard-to-guide, expensive *rear-tine tiller.*

Now there's Mantis... the 20 pound wonder that makes every gardening job a breeze! Mantis *starts* with a flick of the wrist... turns on a dime... weeds an average garden in 20 minutes... and runs all day on a gallon of gas.

Mantis tills a full 8" deep, or delicately cultivates the surface for precision weeding. And, because it's *so easy to maneuver,* women love Mantis! And lots of older people (many of whom had almost given up gardening) find Mantis an absolute joy. *"I'm 82 and I simply couldn't garden any more without it..."* wrote W.R. of Russell, Kentucky (and it's a sentiment we find again and again in letters from Mantis owners).

The secret of Mantis' success is its exclusive "tine teeth" which spin at 240 revolutions per minute *(twice* the speed of most tillers). These *tine teeth* cut through soil, weeds and tough sod like a chain saw cuts through wood.

Women Love Mantis

Mantis is so easy to guide that you can cultivate right around plants, along crop rows and up tight to fences ... without worrying about running into your growing flowers and vegetables.

And, with its easy-on/easy-off *precision attachments,* Mantis quickly becomes a *Planter/Furrower*... a *Border Edger*... a *Lawn De-Thatcher* and *Aerator*... or a superb *Trimmer* for pruning shrubs and hedges.

Best of all, Mantis costs a fraction of what you'd pay for a big tiller!

Get the whole wonderful story on the remarkable Mantis... the little machine that has made gardening such a joy.

OFF-SEASON BONUS

Get a FREE $41.00 Border/Edger! (If you hurry)

Cuts beautiful border edges along drives, walks, and gardens for professionally landscaped finish.

3-WEEK HOME TRIAL MONEY BACK IF NOT DELIGHTED

for formal description, and he named it *Trigonia margaritacea* in 1804 (*margarita* is a Latin pearl, and the interior of a trigonian shell shines with a beautiful pearly luster). But since 1804 lay squarely between Lamarck's initial (1802) and definitive (1809) statement of his evolutionary theory, he also used his short paper on *Trigonia* to sharpen and defend his developing transmutationist views.

Most fossil trigonians are ornamented with concentric ridges at their anterior ends (enclosing the mouth and digestive apparatus) and radial ribs on the rear flank. A single strong rib usually separates these two areas. But all modern trigonians cover their shells entirely with radial ribs (although the embryonic shell still bears traces of the ancestral concentrics). Lamarck seized upon these differences to claim that changing environments had pressed their influence upon the shell. The shell had then altered in response and the animal within passed the favorable change to future generations by "Lamarckian" inheritance.

> They have undergone changes under the influence of circumstances that act upon them and that have themselves changed; so that fossil remains . . . of the greatest antiquity may display several differences from animals of the same type living now but nevertheless derived from them.

(But Lamarck had only demonstrate that the fossils looked different from th moderns. Any theory could account f this basic datum in the absence of furth information—evolution by use and disus by natural selection, or even re-creation b God for that matter.)

Lamarck then proceeded to extrac more from modern trigonians to buttres other pet themes. He was, for example, partisan at the wrong end of a great debat resolved a decade later to his disadvantag by Cuvier (see my column of Jun 1982)—does extinction occur in nature Human rapacity, Lamarck believe might exterminate some conspicuou beasts, but the ways of nature do not in clude termination without descent (La marck, as a transmutationist, obviousl accepted the pseudoextinction that occu when one form evolves into another). La marck gave the old arguments against ex tinction a novel twist by embedding hi justification within his newfangled evolu tionary views. How can extinction occur all organisms respond creatively to chang ing environments and pass their favorabl responses to future generations in th form of altered inheritance?

Yet Lamarck's conviction was sorel challenged by burgeoning data in his ow field of marine invertebrate paleontology So many kinds of fossils are confined t

The fossil trigonian (left) has both concentric and radial ribs, while the living trigonian (right) has only radial ribs.

A powerful new work created in the rich tradition of bronze horse sculpture.

An original sculpture dramatically revealing Monroe's love and knowledge of horses.

Horses have always been a very special part of Lanford Monroe's life. There has never been a time when she hasn't owned or worked with them. And, as an experienced equestrian, she has the most profound understanding of their inner spirit as well as their physical beauty. It's no wonder, then, that her enormous artistic talent finds its finest expression in the extraordinary bronze sculptures she creates portraying these magnificent creatures.

Now, The Franklin Gallery takes pleasure in announcing "The Intruder," a compelling new work by Lanford Monroe—one that confirms her dominance among the great horse artists of our day.

In this original sculpture, a stallion and his mare—their peaceful browsing shaken by an unfamiliar sound or scent—stand alert. It is a moment of high drama and primal impact, when natural curiosity is tenuously balanced by the instinct for survival. The scene is portrayed with complete and stunning realism—the quality most highly valued by knowledgeable collectors of bronze horse sculpture.

To capture every detail of the artist's work, "The Intruder" will be crafted in cold-cast bronze. Each piece will be *individually* shaped from a carefully prepared sculptor's blend of powdered bronze and resins, then meticulously *hand-finished* to achieve the lustrous patina that is characteristic of the finest bronzes.

This important new sculpture is available only by direct application from The Franklin Gallery. And there is a limit of one per order.

Displayed in the home, this vibrantly life-like work will be enjoyed, admired—and talked about—by all who see it. A superb example of horse sculpture at its exciting best.

You need send no payment now, to acquire "The Intruder." Simply return the accompanying Order Form to The Franklin Gallery, Franklin Center, PA 19091, by February 28. 1985.

rocks of early periods. Where are their descendants today? Lamarck offered the only plausible argument in a world with few remaining terrae incognitae—they live still in the unexplored depths of the sea. Since Lamarck reveals his own discomfort with such an ad hoc solution in the form of a defense too often and too zealously repeated—recall Shakespeare's "the lady doth protest too much, methinks"—we may take as genuine his delight in *Trigonia* as a real case for a generalization devoutly to be wished: "Small species, especially those that dwell in the depths of the sea, have the means to escape man; truly among these we do not find any that are really extinct." Lamarck then ends his paper by predicting that a large suite of creatures apparently extinct will soon be found at oceanic depths. We are still waiting.

Since Lamarck's argument centers upon an explanation for why creatures still living yield no evidence of their continued vitality, we should not be surprised that the Cenozoic gap inspired no commentary at all. We must assume that trigonians spent the entire Cenozoic safe in the bosom of Neptune, full fathom five hundred or more, and unrecorded in a fossil archive of shallow-water sediments.

Charles Darwin, leading evolutionist of the next generation, selected yet another aspect of living trigonians—their geographic distribution—to bolster a different theme dear to his view of life. Darwin's creationist opponents, as we shall see, rendered the history of life as a series of static faunas and floras separated by episodes of sudden extirpation and renewal. To confute this catastrophist credo, and to advance his own distinctive and uncompromisingly gradualist view of nature, Darwin argued that the extinction of a group should be as smooth and extended as its origin. A group should peter out, dwindle slowly, decrease steadily in numbers and geographic range—not die in full vigor during an environmental crisis. What better evidence than a family once spread throughout the world in stunning diversity but now confined to one small region and one single species. In his private essay of 1844, precursor to the *Origin of Species* (1859), Darwin wrote: "We have reason to believe that . . . the numbers of the species decrease till finally the group becomes extinct . . . the *Trigonia* was extinct much sooner in Europe, but now lives in the seas of Australia."

(We now regard this claim for extinction of large groups as gradual dwindling in the face of competition from more successful forms—the central theme of chapter 10 in the *Origin of Species*—as among the least successful of Darwin's major arguments. Darwin may have feared that mass extinction supported the creationist view of debacle followed by divine reconstitution. But mass extinction may also clear the way for subsequent, vigorous periods of *evolution*. Again, as so often, Darwin's commitment to gradualism restricted his options for legitimate evolutionary hypotheses.)

Darwin followed Lamarck in dismissing the Cenozoic gap as an artifact of our imperfect fossil record (I can, indeed, imagine no other option for an evolutionist committed to genealogical connection). But Darwin was explicit where Lamarck had been silent. Darwin also tried to accentuate the positive by arguing that the rarity of such long gaps strongly implied their artificial status. He wrote in the *Origin of Species*:

> A group does not reappear after it has once disappeared; or its existence, as long as it lasts, is continuous. I am aware that there are some apparent exceptions to this rule, but the exceptions are surprisingly few, so few that . . . the rule strictly accords with my theory.

Creationists, meanwhile, looked at *Trigonia* from the other side. They treasured the Cenozoic gap and found nearly everything else puzzling. The major creationist thinkers tended to agree that life's history had been episodic—a series of stages separated by sudden, worldwide paroxysms that removed the old and set the stage for the new. But they divided into two camps on the issue of progress. Did each new episode improve upon the last—was God, in other words, learning by doing? Or had life maintained a fairly consistent complexity throughout its episodic history? Progressionists and nonprogressionists found different messages in *Trigonia*.

James Parkinson, England's leading progressionist (though he switched allegiances later on), chose *Trigonia* as a premier example in his *Organic Remains of a Former World* (1811). He read the Cenozoic gap literally, extracting from it the congenial message that life's history features a series of creations not connected by ties of genealogy and physical continuity.

But *Trigonia* also presented a special problem for Parkinson. He argued that each successive episode of creation had been marked "with increasing excellence in its objects," thus matching in all ways but one the Mosaic progression from chaos to Adam as described in Genesis. "So close indeed is this agreement, that the Mosaic account is thereby confirmed in every respect except as to the age of the world" (a problem then resolved by a

orical interpretation of God's six cre- "days"). Now a *Trigonia*, as some say about roses, is a *Trigonia* (subtle- evident to the professional eye aside). should a modern shell with radial alone be better than a fossil represen- e with radials and concentrics? Why he modern versions superior, as Par- on's theory of progressive creation re- ed? Parkinson was evidently troubled. e summary statement to his three-vol- work, he devoted more space to *onia* than to any other genus. He hed at the one available straw, but ly without conviction. At least the ern trigonians are different. "*Raffini- st der Herrgott*" (Subtle is the Lord), nstein said later. We don't know why, different must be better:

shell, although really of this genus, is different species from any shell, which been found in a fossil state. So that none e species of shells of this genus, which known in a fossil state, have, in fact, found in any stratum above the hard k [the Cretaceous, or last period of di- urs], or in our present seas.

ouis Agassiz, most able of all tionists, followed Parkinson's personal e in reverse. He began as an advocate ogress in each successive creation and d by defending the earliest of God's tures as fully up to snuff (largely be- e he despised Darwinism with such ion and felt that any admission of ress would bolster the evolutionary e). For him, therefore, the apparent of improvement in modern trigonians d no problem, while the Cenozoic gap ght nothing but pleasure and con- ation. In the major pre-Darwinian k on these clams, his *Mémoire sur les onies* (1840), Agassiz argued explic- hat a Cenozoic gap, if conclusively af- ed, would effectively disprove evolu- (quite a cogent claim, by the way):

absence of *Trigonia* in Tertiary [Ceno- strata is a very important fact for dis- ons of the origin and relationships of ies of different epochs; for if it could day be shown that *Trigonia* never ex- throughout the entire duration of Ter- time, it would no longer be possible to tain the principle that species of a ge- living in successive geological epochs derived from each other.

ut Agassiz well understood the dis- forting uncertainty of negative evi- e. Find one nasty, ugly little Cenozoic nian tomorrow, and the entire argu- collapses. So Agassiz decided to r his rear and disclaim: No Cenozoic nian is dandy; but future discovery of nozoic trigonian would prove nothing. may, after all, ordain temporal con- tinuity among a group of related, created forms.

Although his passage is an exercise in special pleading, it also contains one of the most succinct and eloquent defenses ever written for the Platonic version of creationism.

> Although I now invoke this fact [the Cenozoic gap] to support my conviction that the different species of a genus are not variants of a single type . . . the discovery of a Tertiary trigonian would still not demonstrate, to my eyes, that the relationship among species of a genus is one of direct descent and successive transformation of original types. . . . I certainly do not deny that natural relationships exist among different species of a genus; on the contrary, I am convinced that species are related to each other by bonds of a higher nature than those of simple direct procreation, bonds that may be compared to the order of a system of ideas whose elements, developed at different times, form in their union an organic whole—although the elements of each time period also appear, within their limits, to be finished products.

In summary, as Darwin's revolution dawned in 1859, the supposedly pure and simple little fact of modern trigonians stood neither as arbiter nor slayer of theories but as touted support for all major conflicting and contradictory views of life—for evolution by Lamarckian and Darwinian agencies, and for creationism in both progressionist and directionless versions. How can something so important be so undecisive? Unless Huxley's heroic vision of raw empiricism triumphant rarely describes the history of ideas or even the progress of science. Percepts do not create and drive concepts; but concepts are not intractable and immune to perceptual nudges either. Thought and observation form a wonderfully complex web of interpenetration and mutual influence—and the interaction often seems to get us somewhere useful.

The *Trigonia* story has a natural ending that should be conventional and happy, but isn't quite. The resolution is not hard to guess, since Darwin's vision has prevailed. The elusive Cenozoic trigonian was found in Australian rocks—at just the right time, in 1865, when nascent evolutionism needed all the help it could get.

H.M. Jenkins, a minor figure in British geology, explicitly defended Darwin in describing the first Cenozoic trigonians. He interpreted the happy closure of the Cenozoic gap as a clear vindication of Darwin's characteristic attitude toward the fossil record and as direct support for evolution. Darwin viewed the fossil record as riddled with imperfections—"a history of the world imperfectly kept . . . of this history we possess the last volume alone. . . . Of

HOW A MOMENT OF LEARNING CAN INSPIRE A LIFETIME OF ACHIEVEMENT.

Watch a child the moment a fresh idea begins to take hold. Curiosity gives way to discovery. And with it comes the exhilaration of knowing something special and new.

Thus the reason for a series of films about math, science, and economics, all funded and distributed by Phillips Petroleum. In them, learning is pictured not as a survival skill, but as a lifelong passion that can thrill, inspire, and ultimately, reward.

Since 1976, millions of young people have seen "American Enterprise" and "The Search for Solutions." Shortly, many will be seeing "The Challenge of the Unknown." To find out more about these films, write: Phillips Petroleum Company Public Affairs Department Bartlesville, Oklahoma 74004.

It's our hope that with the help of a little illumination, whether from a film, teacher, or just an experience, young people can be encouraged to think, and do, the impossible.

this volume, only here and there a sho chapter has been preserved; and of eac page, only here and there a few lines" (*O igin of Species*, 1859). Gaps, as the ol saying goes, represent absence of ev dence, not evidence of absence. Jenkin wrote, linking the newly discovered Ceno zoic trigonian to this fundamental Da winian prediction:

Every paleontologist believes that, when genus of animals is represented by specie occurring in strata of widely different age it must have been perpetuated by some on or more species during the whole of the in tervening period. . . . The only rationa meaning that has ever been attached to th presumed general law . . . is that the pe petuation of the genus . . . has been due t "descent with modification." *Trigoni subundulata* [the formal name for the Ce nozoic trigonian] is one of the links hithert wanting; first, in explanation of the exi tence of the genus *Trigonia* in the Austra lian seas of the present day; and secondl as showing that the great gap which befor existed in its life-history was . . . simply consequence of the imperfection of ou knowledge of the geological record.

Finally, a personal confession in closing This column has been an exercise in sel indulgence and expiation. I put togethe the trigonian story at the very beginning o my professional career (when I was jus barely big enough to pay full price at th stadium). I published a rather poor ac count in a technical journal in 196 (frankly, it stunk).

I got part of the story right. I did recog nize that everyone managed to slot the liv ing trigonian into his system and that sim ple, single facts did not (at least in th case) undo general theories. But I got th end all wrong because the traditiona Huxleyan view still beguiled me. I told th happy ending because I read Jenkins quote and took it at face value—as an evo lutionary prediction fulfilled and an em pirical vindication provided. I forgot (o hadn't yet learned) a cardinal rule o scholarly detection: Don't only weig what you have; ask why you don't see wha you ought to find. Negative evidence important—especially when the record sufficiently complete to indicate that a absence may be genuine.

I now read the Cenozoic discovery quit differently, because I have confronte what should have happened but didn't. Darwin's vindication required a set o new, clean, pristine, unexpected facts then why didn't the Cenozoic trigonian in spire a wave of rejoicing? Darwin had pre dicted it; Agassiz had invested much hop in its nonexistence.

Sure, Jenkins said the right things in hi article; I quoted them and regarded m

sk as complete. But the key to the story s elsewhere—in the nonevents. Jenkins rote a two and a half page note in a minor urnal. No one else seemed to notice. arwin never commented, though the *Or-in of Species* still had several editions to n. *Trigonia* did not become a textbook xample of evolution triumphant. Most riously, Jenkins did not find the Ceno-ic trigonian. It was unearthed by Fred-ick McCoy, an eminent leader of Aus-alian science, the founder and head of e Museum of Natural History and Geol-gy in Melbourne. He must have known hat he had and what it meant. But he dn't even bother to publish his descrip-on. I should have taken my clue from the ening lines of Jenkins's paper, but I ssed them by:

ne very interesting discovery of a species *Trigonia* in the Tertiary deposits of Aus-alia has in England remained entirely in e background, and I have been several mes surprised at finding students of Ter-ary paleontology, generally *au courant* ith the progress of their special branch of ience, unacquainted with the circum-ance. Its importance, in a theoretical oint of view, is beyond all question, hence e deep interest always exhibited by those whom I have spoken on the subject.

I had, in short, succumbed to the view I as questioning. I had recognized that the iginal discovery of the living trigonian ended no theory, but I had let the Ceno-ic fossil act as a Huxleyan nasty fact be-use Jenkins had so presented it. But hen we consider what the Cenozoic igonian did *not* provoke, we obtain a ore general and consistent account of e entire affair. The living trigonian anged no theory, because it could fit owever uncomfortably) with all major ews of life. The Cenozoic trigonian did ot prove evolution either, because gassiz's position of retreat was defen-ble (however embarrassing) and because volution was too big a revolution to rely itically on any one datum. *Trigonia* dn't hurt, but a multitude of fish were ying, and one extra clam, however clean nd pretty, didn't bring the meal to perfec-on (I shall anticipate a suitable recipe ext month, Mr. Sokolov).

Sherlock Holmes once solved a case be-use the dog didn't bark, but would have unded off had it been a dog. Nonevents atter, not only the new and nasty facts. Which reminds me: I must have looked at thousand periwinkles this morning. Still lefties. Maybe someday.

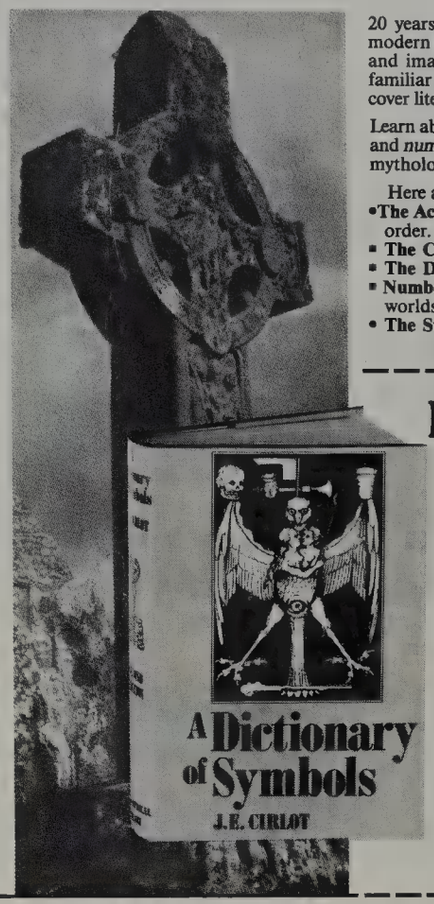
A Very Unusual Dictionary of the Origin of Symbols.



20 years ago, Juan Eduardo Cirlot, the leader of the School of Barcelona modern art movement, assembled a fascinating dictionary of symbolic words and imagery. This dictionary soon became a classic. These mysterious and familiar symbols, drawn from the religions, arts and beliefs of East and West, cover literally centuries of symbolic imagery spanning ancient times to modern.

Learn about the universal fascination with the *dragon;* the subtle power of *colors* and *numbers;* the ancient mysteries of *alchemy,* the *Tarot,* and the *Cabala;* about mythology, cosmology, and dreams and more.

Here are just a few surprising facts about symbols you will find in this book:

- **The Acrobat.** The symbol of reversal, with the power to upset the established order.
- **The Crow.** The great civilizer and the creator of the visible world.
- **The Dance.** The universal symbol for creation.
- **Number Nine.** The triplication of the triple—a complete image of the three worlds: the corporeal, the intellectual, and the spiritual.
- **The Stranger.** Stands for the possibility of unseen change.

A Black Hole for Sure?

Astronomers have the best evidence yet

by Stephen P. Maran

For years astronomers have tried to learn if black holes really exist. At least one observed object, the X-ray source Cygnus X-1 in the Milky Way, is widely regarded as a black hole, although that conclusion is not beyond doubt. However, recent observations provide near-certain evidence that a binary star associated with the powerful X-ray source LMC X-3, in the Large Magellanic Cloud galaxy, contains a black hole. (A black hole is a star that has collapsed to a diameter of just a few dozen miles. Its gravity is so powerful that not even a ray of light can escape, so the collapsed star cannot be seen—hence the term black hole.)

Since black holes are invisible, astronomers try to detect them indirectly by means of their effects on companion stars in binary systems (two stars that orbit each other because of mutual gravitational attraction). Most stars are members of binary systems, so we assume that many black holes are binary stars as well. When observing a binary system composed of an ordinary star and a black hole, we would expect to find the ordinary star and its unseen companion in orbit around a common center of mass. The orbital velocity of the ordinary star would help us estimate the mass of the unseen companion: the faster the ordinary star goes, the more massive its companion. The greater the mass of an ordinary star, the brighter it shines, so that a sufficiently high mass in a star whose light is not detected can be the telltale clue that the unseen star is a black hole.

In close binary stars, mass is often transferred from one star to the other. If a close binary system contained a black hole, gas streaming toward the hole from the companion star would form a doughnut-shaped structure around the hole. As the gas in the doughnut spiraled inward, it would be compressed by the powerful gravity of the black hole and would get denser. Since compression produces heat, the doughnut gas would become very hot and would therefore shine brightly in X-rays. Thus, binary stars that produce X-rays are considered prime candidates for study as possible locations of black holes. In particular, the X-ray source Cygnus X-1, extensively monitored by Uhuru, an orbiting X-ray satellite observatory launched in 1970, was found to be associated with an unseen member of a binary star in our galaxy, the Milky Way. Analysis suggests that the unseen companion is probably a black hole, and recent textbooks describe it as such. Nevertheless, the unseen star in the Cygnus X-1 binary is much less massive than its visible companion, a supergiant star.

Conceivably, the unseen object in the Cygnus X-1 binary is a relatively ordinary star, lost in the glare of its companion supergiant. However, a variety of observations are inconsistent with this hypothesis, and most astronomers believe the object to be a black hole. Nevertheless, a nagging doubt remains. This concern about Cygnus X-1 does not apply to the unseen member of a binary system associated with the X-ray source LMC X-3. In that binary system, the unseen member is more massive than its visible companion star. If it were an ordinary star, it would far outshine its companion and would thus be seen.

The mere observation of X-rays from a binary star does not necessarily imply that a black hole is present, since two other types of small, dense stars—neutron stars and white dwarfs—are sometimes also surrounded by accretion disks (as the in-flowing doughnut-shaped gas structur are called) that glow in X-rays. Whi dwarfs, however, cannot exceed about 1 times the mass of the sun, and neutr stars probably do not exceed about 4 tim that mass, whereas even the visible mer ber of the LMC X-3 binary star excee these mass values.

The recent conclusion that the LMC 3 binary system contains a black ho comes after nearly fourteen years study. The LMC X-3 X-ray source w first observed on September 24, 1970, X-ray sensors on a Thor missile launch to an altitude of more than 185 mil above Johnston Atoll, in the mid-Pacif The observation revealed that the X-r emission from the Large Magellan Cloud was not a diffuse glow from t whole Cloud, as had seemingly been in cated by an earlier rocket observation. I stead, the X-rays appeared to come p marily from two localized sources in t Cloud, although their positions could n be accurately determined. In retrospe most astronomers agree that one of tho two sources was what we now call LM X-3.

In December 1970 and January 197 the Large Magellanic Cloud was repe edly scanned by Uhuru. Those scans tablished the existence of three princip X-ray sources in the Cloud, designat LMC X-1, LMC X-2, and LMC X-3. T positions of the sources were measur well enough to show that they were not c incident with any of the prominent stars cataloged nebulae in the Cloud. T Uhuru investigators, a team of astron mers from American Science and En neering (a private research and manufa turing company located in Cambridg Massachusetts), found that LMC X-1 a

LMC X-3 (which correspond to the two X-ray sources detected by the Thor payload) "are two of the brightest X-ray stars ever observed." It thus became of great interest to learn what kind of stars they were. To do that, it was necessary to pinpoint the X-ray sources and learn which of the numerous stars in their general vicinities were associated with them.

The Uhuru measurements established that LMC X-3 was located within a limited area in the sky, called the error box. In 1973, astronomers from the Harvard-Smithsonian Center for Astrophysics, also in Cambridge, traveled to the Cerro Tololo Inter-American Observatory near La Serena, Chile, to investigate stars in the LMC X-3 error box. They found no evidence for an association of any observed star with the X-ray source, but pointed out a ninth-magnitude star as a promising candidate.

The annual index for
NATURAL HISTORY, VOLUME 93
(January through December 1984)
may be obtained by writing to:

INDEX
Natural History
Central Park West at 79th Street
New York, N.Y. 10024

Observations with two X-ray telescopes on the satellite Copernicus, also made in 1973, ruled out the ninth-magnitude candidate star. More precise than the Uhuru data, the Copernicus measurements reduced the size of the error box within which LMC X-3 must be located. The ninth-magnitude star was outside the borders of the smaller box.

Nevertheless, the reduced LMC X-3 error box did contain many stars much fainter than ninth-magnitude, five of which were observed from the South African Astronomical Observatory at the Cape of Good Hope. In November, 1974, the South African observers reported that one of the five, a previously uncataloged star of seventeenth-magnitude, stood out by virtue of its blue color and slight but certain increase in brightness over four nights of study. They proposed this star as the most likely candidate for association with LMC X-3.

As astronomers worked to pinpoint the optical counterpart of LMC X-3, interest in this X-ray source increased, thanks to additional measurements by Copernicus and by an X-ray telescope on the satellite OSO-7 (the seventh Orbiting Solar Observatory) during the 1970s. These findin showed that LMC X-3 had brighten since the Uhuru observations were ma in 1970–71 and now surpassed LMC X as the brightest X-ray source in the Lar Magellanic Cloud. The X-ray source tensity of LMC X-3 continued to chang varying by as much as a factor of ten, a cording to observations by the British ray satellite Ariel 5, reported in 1977. its brightest, LMC X-3 was perhaps t strongest stellar X-ray source yet foun

Further measurements from South A rica showed that the seventeenth-mag tude star seemed to vary erratically, light changing by as much as 60 perce However, there was no proof that it w the optical counterpart to LMC X-3, the South Africans had suggested. A rect correlation between changes in visi light and in X-ray intensity could be tak as proof of the association, but no eviden of correlated X-ray and visible lig brightness changes was obtained. Instea astronomers again turned to positio measurements in their search for the vi ble counterpart to LMC X-3.

A new, more powerful X-ray satelli HEAO-1 (the first High Energy Ast physics Observatory) scanned LMC X about 700 times during a three-month p riod in the summer and fall of 1977. Tho observations reduced the error box arou LMC X-3 by about a factor of three fr that based on the Copernicus measu ments. The seventeenth-magnitude va able blue star was one of the two bright stars in this smaller error box. A spect gram of the other star, obtained in Mar 1978, with the 141-inch telescope at t European Southern Observatory on Cer La Silla in Chile, indicated that that s was probably just a foreground object our own Milky Way, with no interesti properties. A second three months HEAO-1 observations narrowed t LMC X-3 error box still further. In th error box, the seventeenth-magnitude s was both the bluest and the brightest o ject. The hunters were closing in.

By November 1982 the identificati of the seventeenth-magnitude blue s and the X-ray source had been confirme thanks to measurements by the Einst satellite, the most powerful X-ray obser tory yet launched. The Einstein da showed that the star and the X-ray sou were coincident. During that month, cause the coincidence showed that t blue star was associated with the X-r source, a crucial series of thirteen spect grams of the star was obtained with t 158-inch telescope at Cerro Tololo. T observers, all experts on stellar spectr copy, were Anne P. Cowley (now at A

zona State University in Tempe) and David Crampton and John B. Hutchings, both of the Dominion Astrophysical Observatory in Victoria, British Columbia. They compared the thirteen spectra with each other and with a few earlier observations of the star, extending back to 1978, and discovered that the lines in the stellar spectrum move rhythmically back and forth in wavelength, with a cyclic period of about forty hours.

The cyclic changes in the spectral lines were strong evidence that the blue star follows an orbit with a period of about forty hours. The Doppler effect makes the lines shift with the same period.

The most striking aspect of that newfound orbital motion was its high speed. The seventeenth-magnitude blue star, with an estimated mass of about six times that of the sun, is charging around its orbit at more than 500,000 miles per hour, indicating that its unseen companion star, which has to fit inside that orbit, is even more massive; the best estimate is that the unseen star has ten solar masses. No star of that mass (other than a black hole) would fit in the orbit of the blue star, and even if it did, it would far outshine it; yet no other star is shining there.

Other evidence supporting the identification of the unseen object as a black hole comes from observations of the X-ray spectrum of LMC X-3, made with HEAO 1. According to Nick White, of the European Space Research and Technology Center in Noordwijk, Holland, and Frank Marshall, of the Goddard Space Flight Center in Greenbelt, Maryland, who made a careful study of LMC X-3, its X-ray spectrum agrees with theoretical predictions for the spectrum of radiation from gas spiraling in toward a black hole.

The powerful gravity of the presumed black hole would deform the seventeenth-magnitude blue star, elongating it in the direction of the black hole. Confirmation came in January 1983, when two astronomers at the University of Amsterdam reported on observations made with a sixty-inch telescope at the European Southern Observatory. They found that slight variations in the brightness of the star repeat periodically as it goes around its forty-hour orbit. The brightness changes indicate that the diameter of the star is larger along the axis connecting it to the hypothesized black hole than it is at right angles to that axis. As Cowley, of the spectroscopy team, wrote later, "The gravitational pull of the . . . black hole . . . is so strong that the star is distorted into an egg shape." When the axis is broadside to the earth, the egg-shaped star looks brighter because the long side of the egg is facing the earth; when the axis points roughly toward or away from the earth, the small end of the egg is facing us and the star seems fainter. The degree of distortion of the seventeenth-magnitude star, inferred from these variations in its brightness, is what would be expected if its unseen companion had ten times the mass of the sun.

In summary, much evidence supports the conclusion that the unseen object in the LMC X-3 binary system is a black hole: the rapid orbital motion of the companion blue star; the periodic brightness variations of the blue star, from which its distorted shape is inferred; the deduced mass of the unseen object; its small size inferred from the necessity of fitting within the small orbit of the blue star; that the object *is* unseen; and the strength and spectrum of the X-rays. In view of all this evidence, it seems that at least one black hole has now almost certainly been found.

Stephen P. Maran is a senior staff scientist in the Laboratory for Astronomy and Solar Physics at NASA's Goddard Space Flight Center in Greenbelt, Maryland. The opinions expressed here are his own.

Take Action

Action Series Binoculars – from Nikon – with that breathtaking Nikon quality, optics that seem to illuminate the scene! They feature fast action tracking focus with just a small turn of the extra large focus knob. Rugged, lightweight, sharp, clear, brilliant – they're Nikons! When you take to the outdoors – take Action! 7x35, 8x35, 7x50, 10x50. Surprisingly affordable Nikon Action Series Binoculars at better sporting goods, discount and department stores, and catalog showrooms.

See Them Now

by Thomas D. Nicholson

Our best, if not the most comfortable, views of the stars usually come in the winter months. The main reason, of course, is the long winter nights, which enable us to see the sky in the early evening and late morning, dark hours when we are ordinarily stirring about. In addition, winter skies can be exceptionally crisp and clear, especially at their coldest when they hold so little moisture. Even the winter full moon cooperates, in that its very high path results in less scattering of moonlight in the lower, denser air through which the summer full moons shine all night long. Adding to all this, cyclical changes in the earth's orbit have combined in our era to point us, on winter nights, toward the brightest of our stars, which extend in a great sweep from Canopus in the south (below the Southern Horizon for most of us) to Capella in the north.

We will also enjoy the best of all the evening stars, Venus, in its optimal posture in the Northern Hemisphere's evening sky. This usually comes in February and March, when the ecliptic and orbit of Venus climb steeply upward from the west in the after-sunset sky. We owe to this Venusian posture our spectacular views of the planet this month, and of Mars near it, even though the latter, far from its opposition with the sun, isn't very bright.

Saturn and Jupiter improve their positions as morning stars this month. Saturn, in Libra, is up by midnight at month's end, the brightest "star" in its constellation. Jupiter, after passing the sun in mid-January, lets its brilliance speak for it in the morning. By the end of February it is easily seen in the southeast before sunrise.

Events in the calendar are given at local time unless otherwise indicated.

February 1: The waxing gibbous moon, three days past its first-quarter phase tonight, brightens early February nights. Today, it is near the border of Taurus and Gemini, midway between Taurus's reddish star Aldebaran, to the right, and the twin stars of Gemini, Pollux and Castor, to the left. The bright star above the moon, at the apex of a triangle that includes Aldebaran and the twins at its base, is Capella, in Auriga.

February 3: The brighter, fatter moon, below and in line with the twin stars, forms a threesome with Pollux and Castor.

February 4: Tonight's moon helps in finding the twins again, and also Regulus, the brightest star of Leo. The moon is centered between them, bright enough to dim the fainter, nearby stars. Regulus, to the moon's left, is under a circular group of stars (forming a backward question mark with Regulus as the dot), where the head of Leo would be.

February 5: Full moon, at 10:19 A.M., EST, is in Leo, above Regulus.

February 7: The moon is at perigee (nearest the earth) tonight. While the moon has pointed out the brighter stars higher in our sky this month, Venus and Mars have continued as evening stars fairly low in the west for several hours after sunset. Venus will be visible in twilight, and when the sky around it darkens, Mars is the only obvious object near it. If you observed the two planets in January, you will notice how much closer they are now. Venus passes Mars (conjunction) about 9:00 P.M., EST, moving east of it. But watch what happens later in the month.

February 8–10: The waning moon rises shortly before midnight on the 8th and 9th and drifts through Virgo on the mornings of the 9th and 10th, where it marks the bright star Spica. The moon passes th star from right to left on the 9th.

February 12: Last-quarter moon, a 2:57 A.M., EST, is in Libra, where you wi see it after it rises about an hour past mid night. The bright object above it is Saturn

February 13: The reddish star below th moon this morning is Antares, in Scorpius

February 15: The stars below the cre cent moon, in Sagittarius, trace the ou line of a teapot, with the moon very nea the peak of the lid. Look before daybrea dims the stars, even though the moon low. Venus and Mars, in the west afte sundown, haven't separated much sinc Venus passed Mars only a week ago. No Mars passes Venus, and the latter slow down in its easterly motion after greates elongation on January 22. In a few night you will see that they are slowly separa ing, with Venus to Mars's right again.

February 17: This is the last morning t see the late crescent moon before it be comes new. You might be able to find Ju piter above it in the early twilight, the firs time the planet has appeared as a mornin star this season.

February 19: Mercury is at superio conjunction with the sun, passing it fron right to left to enter the evening sky. Ne moon occurs at 1:43 P.M., EST, joining th sun in Aquarius.

February 21: Coming out from th sun's glare to the left, the new crescen moon should be visible after sundown near the southern border of Pisces, jus south of the vernal equinox.

February 22: The moon is near Mar and Venus until they all set at about 9:0 P.M. Look above the crescent where th sky is dark enough to see some stars. Mar will be nearest the moon, and brilliant Ve nus much higher.

Free! Royal Albert thimble for joining now.

The Thimble Collectors Club

Now, at modest cost, you can build your own collection of choice collector's thimbles.

Royal Copenhagen...Wedgwood...Lladro...
Ginori...Hutschenreuther...Royal Doulton...
Haviland...these and others of the world's greatest porcelain houses will be represented in your collection.

This lovely glass-domed display stand can be an attractive addition to the decor of your home. It and other unusually fine display pieces are offered by the Club to members.

The finest thimbles are works of art in miniature.

Charming and colorful, they add warmth and appeal to a room. They are family treasures to be passed to daughter and granddaughter. It's no wonder millions of people around the world collect thimbles.

A Lovely Thimble Sent To You Each Month

Now, through membership in the Thimble Collectors Club you can build a collection of the *creme de la creme* of porcelain and china thimbles; a collection which would be practically impossible to assemble on your own.

Each month, you will receive a beautiful thimble. Our representatives are in contact with porcelain houses all around the world. They select only the very best thimbles. Indeed, many of the monthly selections will have been created exclusively for the Club's members.

The thimbles in your collection will bear the names and identifying marks of the great houses that created them. They will reflect the different artistic visions of the various nations and porcelain makers. Thus, the individual thimbles will have infinite variety...yet together they will form a harmonious collection.

A card will accompany each thimble describing the motif on it and the porcelain house which made it.

A Wedgwood thimble in their famous blue Jasper, invented in 1774 by Josiah Wedgwood himself. It depicts their well known Floral Girl. $7.60.

No Risk or Obligation

If you are not delighted with any month's thimble selection, you may simply return it within ten days for full refund. And you may cancel your membership at any time.

Enchantment;" a delightful fairy thimble from Royal Worcester. $7.50.

This traditional Dutch Windmill design is delicately captured in the beautiful 'Blue Chinese' style, by Royal Mosa. *$8.00.*

An Aynsley *Bird thimble in fine English bone china. $6.80.*

Kaiser of Germany has portrayed an exquisitely detailed country scene on this delicate thimble. $7.95.

Haviland *of Limoges presents a lovely violet thimble – perfectly beautiful! $9.50.*

Belleek *of Ireland has hand-painted Shamrocks on this thimble made from their famous Parian china. $7.20.*

Modest Cost

One of the nice things about collecting thimbles is that besides being beautiful, they don't cost a lot. The Club's regular monthly selections typically cost about $7.50 to $9.50.

Send No Money Now

To join the Thimble Collectors Club, just send your application. Enclose no money now. You will be billed for your first monthly thimble selection.

The Thimble Collectors Club reserves the right to select specific designs included in this collection.

February 23: The moon is farthest from the earth about 1:00 P.M., EST.

February 24: The crescent moon crosses the border between Pisces and Aries, and the brighter stars of Aries, Hamal, and Sheratan are above it.

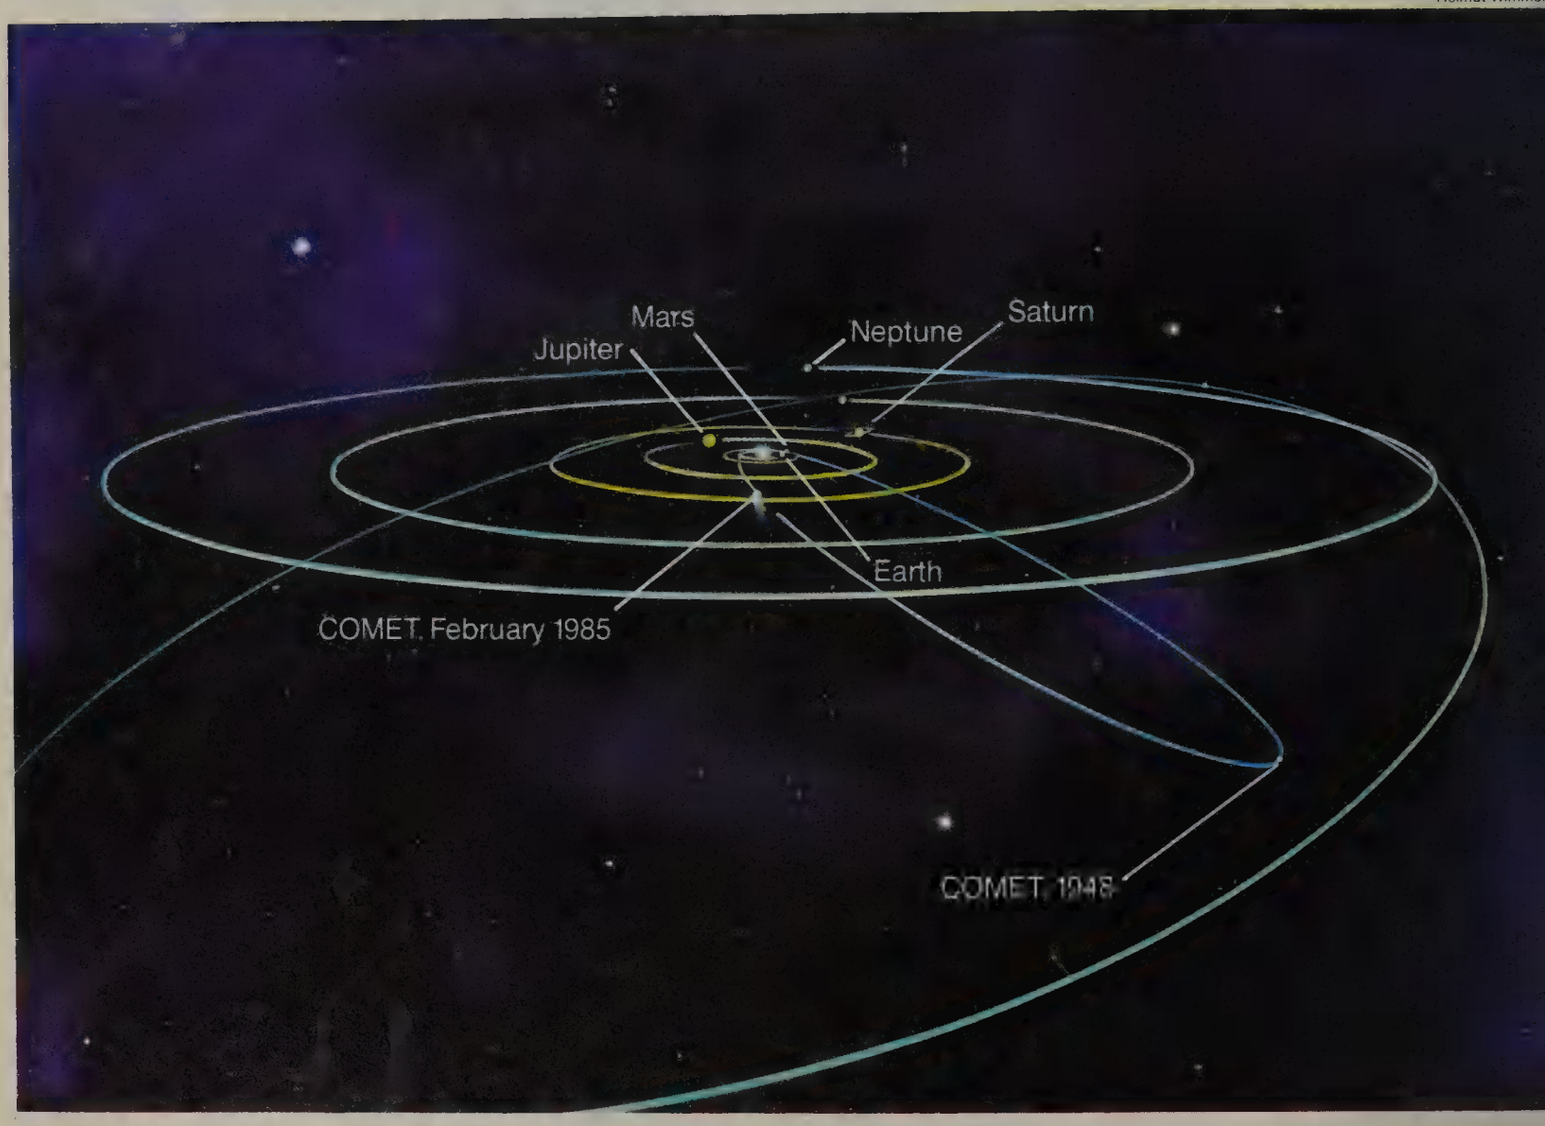
February 26: One day before first quarter, the moon enters Taurus and moves past the Pleiades, the fuzzy cluster of stars sometimes called the Seven Sisters. Look at them with binoculars if possible. Venus, below the moon early in the evening, is at greatest brilliancy in this evening cycle.

February 27–28: The first-quarter moon, at 6:41 P.M., EST, on the 27th, is above Aldebaran, Taurus's brightest star. On the evening of the 28th, the moon is nestled between the two stars that mark the Bull's horns.

Editor's Note: The Sky Map in the January issue shows the evening constellations and stars for this month and gives the times and dates for use.

Halley's Comeback

Helmut Wimmer



Halley's comet returns in 1985/1986. "Celestial Events" will document the comet's journey in a monthly countdown to show you where it is and where, when, and how it can be seen.

We begin the countdown with a view of where the comet has been following its last appearance in 1910. Since then, it has drifted slowly away from the sun in a long, narrow elliptical orbit, reaching in 1948 a point called aphelion, at which it was farthest from the sun, beyond the orbit of Neptune. On its current return, it has been gradually accelerating, and in February 1985, it will be near the orbit of Jupiter (but nowhere near the planet itself, as the illustration shows), heading toward perihelion (nearest the sun) on February 9, 1986. During subsequent months, we will depict the comet as it comes nearer the earth and the sun. Its position will be shown each month relative to the sun and planets, and then relative to the stars of our sky when the comet is expected to be visible to us, until it fades in the spring of 1986.

The very name of the legendary Halley's comet is synonymous with the awe, the mystery, and the drama associated with comets. The most famous of all such objects, with the longest record of appearances, dating back to 250 B.C., Halley returns to the earth's sky every 75 to 76 years. It is named after the eighteenth-century British astronomer Edmund Halley, who in 170 accurately predicted it would return in 1758, after a search of earlier comet sightings led him to believe that several were successive appearances of the same object at regular intervals.

In this month's illustration, the planets are located in their respective orbits, and the orbit of Halley's comet, inclined by seventeen degrees to the earth's orbit, is shown in relation to them. The position of Halley's comet in February is marked by a small cometlike symbol even though the object itself is still small and undistinguished, much like a faint, fuzzy star detectable only by modern instruments. Most of Halley's path lies south of the solar system's plane of orientation. Not until October of this year will the comet move north of the planetary orbits; in March 1986, it will move south again.

INTRODUCING THE "ROUTE OF THE GLACIERS," 7, 10 & 11-DAY CRUISES ON SAGAFJORD AND CUNARD PRINCESS.

Follow the "Route of the Glaciers" with Cunard and you'll see more Alaska than with any other cruise line. These spectacular seven or nine-port cruises go all the way to Anchorage (most others turn back in Skagway) so that you see sights others miss such as the massive Columbia and Hubbard Glaciers and the Kenai Fjord National Park.

You also explore the Inside Passage. And since all cruises begin or end in Anchorage, you have the perfect jumping-off point for Cunard's tours to Alaska's interior without tiresome bus rides.

Sagafjord's 5-Plus Star Alaska

Offering luxurious ten and eleven-day cruises, Sagafjord takes you to the heart of Alaska with distinctive, personalized service, relaxed, single-seating dining, superb cuisine, the "Golden Door Spa at Sea"® and much more.

Cunard Princess, a modern floating resort

Cunard Princess offers simply the best seven-day itineraries. Enjoy fine dining with panoramic sea views, nightclubs, theatre, dancing, a casino, a piano bar and more.

Money-saving air/sea packages, cruise tours

Rates for seven-day Alaska cruises on Cunard Princess begin at $1,225. Sagafjord rates begin at $1,950 for ten-day cruises, $2,160 for eleven-day cruises. Money-saving air/sea packages for cruises and cruise tours are available from 79 cities.

For reservations and information call your travel agent, or mail in the coupon.

*All rates are per person, double occupancy and depend on departure date and city. Taxes not included. Ships' registry: Bahamas.

Cunard, P.O. Box 999

Among the most populous roosts in the world are those of the red-billed quelea of Eurasia and Africa. These birds were photographed at night in Botswana.
Peter Johnson, NHPA

The Birds' Communal Connection

There is relative safety for seniors but some risk for juveniles when huge numbers of birds roost and flock together

by Patrick J. Weatherhead

My memories of Alfred Hitchcock's film *The Birds* have dimmed with the years, but I still remember my sense of wonder at scenes of birds converging, slowly at first, and then by the thousands. And a question persisted in the back of my mind: How did Hitchcock get so many avian extras to assemble in one place, at one time?

I did not have a plausible answer until several years ago, when I saw a communal roost site for the first time in Fort Campbell, Kentucky. I arrived at the site with some colleagues in the late evening before the birds began to appear. Although there was an impressive accumulation of droppings in the pine stand where the birds roosted, our lack of familiarity with roosts made us skeptical about the estimate, issued by the U.S. Fish and Wildlife Service, that the population numbered four million blackbirds and starlings. Our doubts vanished quickly when the sky began to fill with birds all flying directly to the roost and funneling into the trees. Long after there did not seem to be space for one more bird, they continued to pour out of the sky. Communal roosts, I decided on the spot, must have been what Hitchcock filmed.

Roosting is simply a daily period of inactivity—the equivalent in human terms of resting or sleeping. All birds roost; but some roost alone, some roost communally, and some switch from solitary to communal roosting on a seasonal basis. Even among the gregarious species there is further variation in the size, location, and timing of the roosting aggregation.

Attempts to generalize about the survival value of various roosting patterns seem doomed to failure. The size of communal roosting populations, for example, is one of the most variable features of the behavior. At one extreme are the small clusters of creepers or nuthatches that gather at night in tree cavities. At the other extreme are the most populous roosts, involving mind-boggling numbers of birds. Winter blackbird and starling roosts in North America regularly exceed several million individuals. In Africa, the red-billed quelea roosts in numbers estimated in the tens of millions. But the all-time record must go to the now-extinct passenger pigeon, estimated to have had single roosts of more than two billion birds covering an area of several thousand acres.

Both communal and solitary roosting species are well represented throughout the avian kingdom. And, as mentioned above, there are even some species that switch seasonally from solitary to communal roosting. The red-winged blackbird is an example of this behavior. During the breeding season, male redwings are the epitome of intolerance, each defending his territory against trespass by another male. Within weeks of the beginning and end of the breeding season, however, those same males roost side by side every night and remain gregarious throughout the non-breeding season.

Another variation in communal roosts is the choice of roosting habitats. This variation exists even within a single species. The European starling, for instance, has perhaps the most catholic taste in roosting habitats. I have seen starling roosts in cattail, reed, and alder stands in wetland habitats; in pine, cedar, maple, and mixed deciduous stands in upland habitats; and under bridges, on buildings, and in bell towers. When one adds to the list the cliff faces used by vultures, the is-

Barn swallows roost communally but only move close together in cold weather. They also forage together for flying insects.

Frith and Frith; Bruce Coleman, Inc.

lands used by sea birds, and the tree cavities used by creepers, it is apparent that communal roosting cannot be explained on the basis of the characteristics of any particular habitat.

What makes the question of why some birds roost communally so intriguing is the apparent disadvantage of that behavior. Birds are creatures of habit and return to the same roosting sites night after night, month after month, and year after year. Thus communal roosting would seem to provide would-be predators with a predictable and abundant source of food and hunters with an ideal target (witness the extinction of the passenger pigeon by humans). Another disadvantage of thousands of birds returning every night to the same location is that their search for food every morning takes them over the same general area in which they fed the previous day. This should put a substantial strain on the food supply, create competition between roost members, and require them to fly ever greater distances from the roost to find food.

Paradoxically, the same factors that seem to make communal roosting disadvantageous—the ease of predation and the difficulty of finding food—also form the basis of the two major traditional hypotheses proposed to explain the advantages of the behavior. The first of these, the predation-avoidance theory, presumes there is safety in numbers. Consider a bird that roosts alone. If found by a predator, the odds of that bird being eaten are necessarily 100 percent. If two birds roost together and a predator finds them, the odds that either individual will be eaten drop to 50 percent (since predators can presumably only grab one victim at a time), so the birds are clearly better off. Apply this reasoning to roosts that contain thousands or millions of birds. The odds of any individual roost member being taken by a predator are extremely small. The larger the roosting population, however, the easier it should be for predators to find the birds. The noise level, if nothing else, should attract attention. Thus the advantage to individuals in a communal roost only holds if the diminished risk from predators outweighs the increased risk of being ever more easily located as roost size increases. In other words, even if predators have no difficulty capturing some birds in a large roost, the other birds should continue to use that site as long as they are at lower risk than they would be if they roosted alone. Although no good data are available on the predation rates on communal roosting populations, I would expect them to be high. That roosting birds are often densely clumped, and so loathe to leave the roost that humans can capture them by hand, suggests that the birds are easy pickings for skillful predators.

Related to the advantages birds realize by reducing individual predation risks are the advantages they derive while foraging. Most species of communally roosting birds feed in flocks. As in a communal roost, individuals in a flock reduce their

Each black vulture picks its own cactus as the sun goes down in the Sonora Desert.

M.P.L. Fogden

chances of being the victim should a predator attack. In addition, there is evidence that birds in a flock can more quickly detect the approach of predators than can individuals that feed alone, presumably because more eyes are on the lookout. Using trained goshawks as experimental predators, an ornithologist who tested this hypothesis found that larger flocks of wood pigeons detected an approaching goshawk at a greater distance than did smaller flocks, reducing the goshawk's hunting success. Not only are more eyes an advantage in detecting predators; they also enable each bird to spend more time looking for food. The same advantage holds for a bird in a mixed-species flock. Another researcher found that when downy woodpeckers joined flocks of chickadees, titmice, and nuthatches, they reduced their vigilance and increased their foraging rate.

An additional advantage of feeding in flocks is that short-lived food supplies, such as swarms of insects, schools of fish, ripening fruit, patches of seeds, or the carcasses of dead animals, can be more effectively located. The sites where these sources are found are often too large for one individual to search thoroughly in the short time before the food patches are discovered by other animals with similar feeding habits. The suggestion has therefore been made that by feeding in flocks, individuals benefit from the search effort of other flock members despite the disadvantage of competition from them.

Granted that foraging birds can reduce their risk of predation by feeding in flocks, why is it necessary for the flocks to congregate each evening for roosting? One hypothesis is that the roost is used as an information center—a place to learn where the food is located. Observation of a flock of feeding birds indicates that flock members do use each other to locate food. When a few individuals focus their attention on one patch of ground, other birds quickly congregate there. This is the same imitative behavior that causes vultures to gather rapidly at a fresh kill and ducks to be attracted to hunters' decoys. If birds feeding in flocks can find local food patches more efficiently than birds feeding alone, then, according to the information-center hypothesis, those flocks should also be better able to locate food patches over a wider expanse. By roosting together, birds can take advantage of the search by fellow roost members to locate food. An entire flock or a flock member that returns to the roost without finding food need only follow more successful individuals the next day to locate new food patches. Just as those who argue that the principal advantage of communal roosting is the avoidance of predation also concede a secondary advantage to greater success in finding food, so proponents of the roost as an information center concede that a secondary advantage may be the avoidance of predation.

A fundamental problem with the information-center hypothesis is that it con-

Within almost all avian families there are examples of communal roosting. The gregarious rainbow lorikeet of Australia is one of them.

Stephen J. Krasemann

fers an advantage on individuals that "cheat": birds that return to the roost but never share information about food patches they have successfully located. A related question is how birds recognize individuals that have foraged successfully. (Birds don't belch or pat their stomachs after a good meal, so no one knows how they might indicate they have fed well.) The "cheating" problem applies to the older birds, which are more skilled at finding food than their juniors. These older birds would seem to be better off avoiding communal roosts rather than using them and always having to share their food with younger birds that follow them. In large roosts those younger birds are not necessarily related to the older birds, so it is not a case of the older birds sharing food with their offspring.

As I continued to ponder why some birds roost communally, it occurred to me that the shortcoming of the two main hypotheses—predation avoidance and the communal roost as an information center—was that both assume that all birds in a roost are there for the same reason. If one assumes that different individuals might benefit in different ways from roosting together, one arrives at an explanation for communal roosting that is more consistent with both fact and theory.

The problem with the information-center hypothesis is that older birds, which many studies—ranging from pelicans to blackbirds—show are consistently better at finding food, do not seem to gain any advantage from communal roosting. But older birds usually dominate younger ones and are therefore able to displace them from preferred perches in a communal roost. This ability would be highly advantageous if birds spending the night on certain perches were more vulnerable to predators. We know that among birds that breed in colonies, nests on the periphery of the colony usually suffer the highest predation rates, and the suggestion has been made that competition for central nest sites probably forces the younger birds to the periphery of the colony. Such a pattern may also prevail in communal roosts, since a predator entering a roost would probably attack the first birds it encountered on the periphery. Thus, a roost can be thought of as a series of concentric layers of birds, with the lowest-ranking, younger individuals in the outermost layer and the most dominant, older individuals in the center. The efforts of the birds in the vulnerable outer layers to insinuate themselves into the more secure inner layers could account for the high densities of birds in many communal roosts.

Given the advantage to the birds in the center of a roost, why do individuals forced to stay on the periphery join a roost at all and run the higher risk of predation? If dominance and foraging skills are strongly correlated, then the peripheral roost members would be those most in need of information regarding the location of food. As long as the advantage of following dominant roost members to feeding sites outweighs the risks of being killed by a predator, subordinate birds would also benefit by membership in a communal roost. This supposition, combining elements from the two traditional theories about communal roosting, is what I will refer to as the two-strategies hypothesis.

Although we need studies designed to test the specific predictions of this two-strategies hypothesis before its validity and general application can be evaluated, some promising evidence already exists. A study of rooks in East Lothian, Scotland, showed that the older birds dominated younger birds, as evidenced by the older birds' ability to displace the younger birds from perches higher in the roost trees. The researcher interpreted the preference for higher perches as evidence that higher positions were less vulnerable to terrestrial predators, although no data in support of that interpretation was provided. Studies

A flock of yellow-headed blackbirds feeds on insects and seeds. The birds nest in colonies but roost both in groups and solitarily.
Galen Burrell

of brown-headed cowbirds roosting in oak trees on the Rice University campus in Houston, Texas, and studies of red-winged blackbirds roosting in a stand of cattails in a city park in Ottawa, Ontario, have also found that older birds use their dominant positions in the hierarchy to gain access to these presumably safer roost sites. The roosts in both of these studies—unlike the rook roosts in Scotland—were stratified horizontally, rather than vertically, with a disproportionate number of older birds occupying central positions. The advantage to older birds of access to safer roost sites is consistent with the two-strategies hypothesis for communal roosting outlined above.

A dominance hierarchy has also been observed in a mixed-species roost of egrets, herons, and other species in San Blas, Mexico. In this instance, dominance was determined by species rather than age, with the snowy egrets and great egrets displacing the other species of egrets and herons from the higher perches in the roost trees. Again, the higher perches were thought to be preferred because individuals roosting there would be less vulnerable to predation. Interestingly, a study of some of the same species of egrets and herons in Panama revealed that three of the heron species increased their foraging success by feeding near the snowy egrets. When dummies of each species were placed in foraging areas, many more birds were attracted to the artificial snowy egrets than to dummies of the other species, indicating that the snowy egrets were being used to locate food. If subsequent observation at the roosts in Mexico and Panama reveals that the subordinate species in the roost follow the snowy egrets to feeding areas, the two-strategies hypothesis will gain strength.

The best evidence in support of the two-strategies hypothesis was brought to my attention by Danish ornithologist Anders Pape Møller. In a recent study of roosting swallows in Bronderslev, Denmark, Møller found that older birds not only had greater feeding success than juveniles; they were also able to displace juveniles from the lower perches in the reeds in which they roosted, forcing the younger birds to roost in positions that appeared to make them more vulnerable to predators.

Møller's study recorded the foraging success of flocks of swallows feeding away from the roost during the afternoon. Observation at those sites the following morning revealed that the greatest increase in the number of foraging birds occurred where the foraging success had been highest the previous afternoon, and that the increase in flock size was due primarily to an increase in the number of juvenile birds. Interestingly, this pattern of an increase in flock size at sites where foraging had been successful the previous day only held when Møller considered the afternoon foraging success of adult swallows, not juveniles. One might infer that, in some manner we do not yet understand, juvenile swallows in the roost were able to recognize adults that had foraged successfully that day and to follow them to those feeding sites the next morning. That the successful juvenile birds were not followed, in turn, to their feeding areas may indicate that a well-fed adult is a more reliable source of information regarding feeding sites than is a well-fed juvenile.

Because the evidence available to date is consistent with the two-strategies roosting hypothesis, one might expect that the

hypothesis will prove to be valid under most circumstances for most species. But even general explanations of natural phenomena have many exceptions. For example, I have largely ignored the role of temperature in a communal roost. Because their collective body heat loss may raise the temperature within the roost, birds roosting together probably lose less energy at night than those roosting alone. However, independent studies of jackdaws and starlings have shown that the energy the birds save by roosting together does not compensate for the energy expended in flying to and from the roost each day. Nevertheless, for species such as pygmy nuthatches, which gather in well-insulated tree cavities and pack in so tightly that they maintain body contact, energy savings may well be the primary benefit of roosting. Species such as tree swallows, barn swallows, and bank swallows regularly roost communally but form tight clusters within the roost only in very cold conditions. Therefore, communal clustering and communal roosting should perhaps be considered separate phenomena.

This discussion of communal roosting has so far been restricted to birds. But bats also often roost communally. Spectacular aggregations of millions of Mexican free-tailed bats can be seen in the Carlsbad Caverns in New Mexico. Whether all species of bats that roost together do so for the same reasons, and whether those reasons are the same as the ones influencing the behavior of birds, is not known.

My expectation is that as empirical studies of roosting birds catch up with the new two-strategies theory, we will see both general patterns and numerous exceptions. The generalizations would necessarily have to involve predation and food finding because large numbers of birds require large amounts of food—and represent just that for predators. The exceptions to the theory would include those species that huddle only for warmth and probably some species that we predict should roost communally but do not. Careful study of species of the latter type will determine whether they are exceptions that prove the rule or instances that disprove the rule altogether. □

Blackbirds fly across a Louisiana field on their way to their roosting site. The numbers in which they and the red-billed quelea roost are probably among the highest of any extant species.

Roots That Go Out on a Limb

In the rain forest, trees tap into air plants that mass on their branches

by Nalini M. Nadkarni

Seventy feet above the floor of a tropical rain forest, a pink orchid blooms in a pad of soft, gray-green moss held aloft by a stout tree limb. Nestled among the spiky, swordlike foliage of bromeliads, tiny-leafed ferns flicker in the sunlight. A bird's-eye view of the forest canopy offers an aerial parade of plants in extraordinary variety, hidden to all but the keenest observer on the ground below. While they are sometimes known as air plants, these treetop dwellers are generically classified as epiphytes (*epi*, "upon"; *phyte*, "plant") because they grow, not in the earth, but upon the branches and trunks of supporting host trees.

Epiphytes have fascinated botanists and horticulturists for a century, not only because of their diversity—some 30,000 species of plants grow epiphytically—but also because their unexpected presence in the forest canopy of foliage seems an incongruous whimsy of nature.

Contemporary biologists are particularly interested in the place that epiphytes hold within the self-contained ecological community of the forest canopy. Paradoxically, in forests where heavy rainfall leaches nutrients from soil, vegetation grows in profusion. What role do epiphytes play in this highly efficient nutrient-conservation system?

Until recently, epiphytes were thought to be somewhat superfluous to the ecosystem. Traditionally, their relationship to host trees has been regarded as nutritionally neutral: they neither harm nor particularly help one another. Now there is new evidence that epiphytes may offer their hosts direct nutritional benefit in return for treetop support.

Epiphytes take only physical support, not nutrition, from their host trees. Unlike true parasites, such as mistletoe (whose roots burrow through bark and tap into the host tree's vascular system), epiphytes have no direct access to nutrients within their hosts. Nor do they have root systems that, like vines and lianas, compete with surrounding vegetation for their share of nutrients on the forest floor. Rather, epiphytes take sustenance from the trace amounts of minerals in rainwater and dust particles that fall upon them as these nutrients pass through the treetops.

Epiphytic plants of the rain forest canopy encounter feast-or-famine conditions. The supply of essential nutrients, such as nitrogen, phosphorus, calcium, and other mineral elements, is erratic and uneven. Although rain passes through the canopy with some regularity, it moves over branches and trunks rapidly and leaves little residue. Compared with the warehouse of nutrients on the forest floor, the canopy cupboard is rather bare.

In the face of this sporadic supply of nutrients, many epiphytes in temperate and tropical regions have developed structural and physiological characteristics that allow for efficient nutrient gathering and storage. These mechanisms include such structures as absorptive trichomes, hairlike structures on the surface of leaves that aid in water retention, and leaf formations that actually cradle and save water and nutrients. Some of the lower orders of epiphytes, such as mosses, liverworts, and some lichens, are characterized by "poikilohydric" foliage: special guard cells on the plant's surface quickly absorb moisture when it is available, immediately shut down to prevent water loss when exposed to extremes of heat, and then rapidly resume metabolic processes when moisture is again available. These qualities provide some epiphytes with a degree of tolerance to the extreme environmental conditions of the exposed canopy.

As a graduate student in forest ecology at the University of Washington, I studied the relationship between epiphytes and their host trees and focused in particular on how nutrients are stored and then transferred, or cycled, throughout the forest canopy. My investigations were conducted on the west coast of the Olympic Peninsula in Washington, in a classic example of a temperate rain forest. The Olympic Rain Forest, as it is popularly known, lies within the borders of Olympic National Park and shares numerous characteristics with tropical rain forests: it is a multistoried forest of massive evergreens, with abundant rainfall (nearly 150 inches a year) and highly leached, nutrient-poor soil.

The profusion of epiphytes in the Olympic Rain Forest is greater than in any other temperate rain forest in the world and even rivals that of tropical rain forests of South and Central America. Epiphytes upholster the branches and trunks of the Sitka spruce, Douglas fir, red alder, and black cottonwood trees. On the big-leaf maples that grow in wet lowland sites along the park's Hoh River, epiphytes festoon tree limbs like damp green fur, and thick mats of decomposing epiphytic matter, or detritus, form cushions as much as ten inches thick.

The epiphytes of the Olympic Rain Forest belong mainly to the nonvascular and the lower order vascular plants: lichens, mosses, club mosses, and liverworts. With the exception of the licorice fern, higher order epiphytes, such as the orchids, bromeliads, and gesneriads found in tropical regions, do not grow there. The Olym-

Gathering moisture and dissolved minerals from the continuously humid atmosphere, epiphytes, or air plants, cloak the trees in the Monteverde cloud forest of Costa Rica.

Richard La Val

pic Rain Forest does not display the colorful patchwork of flowering epiphytes found in the tropics, yet the diversity of epiphytic mosses and liverworts is remarkably high; more than 130 epiphytic moss species have been documented there. Among the more common species are the *Eurynichium oreganum*, *Isothecium stoloniferum*, and the stepping-stone moss (*Hylocotnium splendens*).

In the past biologists were limited to studying canopy ecology by climbing trees with spikes and ladders, constructing aerial catwalks or free-standing towers, or by simply cutting down trees. Obviously, these methods not only restricted movement within the canopy but also frequently harmed or even killed the trees. In recent years, however, a number of imaginative and intrepid biologists have applied advanced rock-climbing techniques to gain safe access to the treetops and easy mobility within the canopy. Now the world of epiphytes is accessible to all but the most acrophobic.

Climbing into the canopy is quite simple. A sturdy nylon cord is shot over a branch with a crossbow or slingshot, then tied to a standard mountain-climbing rope. This rope is then pulled over the branch and anchored at the base of the trunk or that of a neighboring tree. Wearing a seat harness and leg loops and assisted by special sliding aluminum clamps called Jumar ascenders, the climber can inch up the rope with a minimum of effort. By shooting lines from treetop to treetop, one can use the ascenders to move laterally across the canopy.

Once within the canopy, it is possible to estimate the magnitude of the entire epiphytic community by weighing sample epiphytic mats from selected trees of differing sizes. For example, the fresh weight of live epiphytes on a typical big-leaf maple (height, sixty feet; diameter, forty inches) was 100 pounds. Extrapolating from these figures to the entire maple grove, the dry weight of epiphytes totaled 6,000 pounds per acre, four times the weight of host tree foliage calculated by other researchers in similar forests.

Mineral elements held within this mass of epiphytic growth constitute a considerable portion of the canopy's pool of available nutritional resources. Some of these nutrients, intercepted from rain or dust and held temporarily in epiphytic tissues, are transferred, or cycled, to other parts of the ecosystem: epiphytes fall to the forest floor, decompose, and join the pool of nutrients in the soil; their nutrients are leached from the canopy via rainfall, or the plants are eaten by herbivorous insects and deposited as they die or defecate.

As I continued to peel epiphytic mats from the trees' surface, I made a totally unexpected discovery that suggested yet another means of nutrient transfer. Under the epiphytes, an extensive network of roots crisscrossed the branches and trunk of the maple tree where I was working. The roots penetrated mats of decomposing epiphytes and ranged in size from tender white root tips with tiny root hairs to woody roots three inches in diamete They appeared only beneath layers moist organic matter and were abse where epiphytes tapered off on upp trunk and outer branch surfaces.

Like a spider racing to build its web, slid over the trees on my climbing rop and traced each system back to its point origin: the junction of a branch system the host tree itself. These were map roots. Greatly excited, I realized that he was a shortcut in the rain forest's nutrie cycling system. Host trees were capable tapping the arboreal cupboards in the own crowns.

A typical big-leaf maple with heavy f liage and a diameter of approximate forty inches had canopy roots originati at eighteen points along the trunk, an where from three to forty-five feet abo the forest floor. Some of the roots e

By sprouting roots directly from trunks and branches, rain forest trees exploit the nutrients contained in the cushiony mats of live and decaying epiphytes. Below: A layer of epiphytes has been pulled back to expose a tangle of aboveground roots.

Richard La Val

ended as far as twenty feet out along branches before epiphytic mats and roots erminated. Three canopy root systems branched off in an upward direction; two had descended down the trunk completely and penetrated the forest floor below with no alteration in appearance.

I was eager to learn the extent of this phenomenon. Nowhere in the literature on epiphytes was this hidden root system recorded. How common was canopy rooting? Which trees put forth such root systems? What kind of roots were they, and what did they do? In the following weeks more and more lines dangled from the forest canopy as I expanded my treetop surveys. Ropes were tossed and tied; tools and supplies raced up and down guidelines.

Four of the seven common tree species that grow in the Olympic Rain Forest produce canopy rooting: the big-leaf maple (*Acer macrophyllum*), vine maple (*A. circinatum*), mature red alder (*Alnus rubra*), and black cottonwood (*Populus trichocarpa*). Anatomically, canopy roots were identical to their belowground counterparts. Root sections observed under a microscope revealed cortical cells, xylem and phloem bundles, root caps, and root hairs, all common root structures necessary for absorption and conduction of water and nutrients.

Canopy roots also exhibited the same symbiotic relationships with microorganisms as did the tree's underground root system. One such relationship involved root-dwelling microorganisms that can "fix" nitrogen and make it available to the host tree in usable forms. Through a metabolic process carried on by the microorganism, atmospheric nitrogen is transformed into nitrate and ammonium, both essential to plant growth. This relationship is manifested by the formation of nodules, or grapelike tissues, that appear on belowground roots. Peeling away epiphytic mats on mature red alder trees, which are known to be capable of fixing nitrogen, I exposed roots high above the forest floor that displayed well-developed nitrogen-fixing nodules.

Canopy roots of the big-leaf maple demonstrated yet another symbiotic association, called mycorrhizae, common to belowground roots. In this case, the vegetative parts of a fungus—threadlike filaments called hyphae—attach themselves to tree roots and, in a process not entirely understood, seem to enhance a root's capacity for taking up mineral nutrients from its surroundings. Some canopy roots were also mycorrhizal.

Extensive investigation has revealed that canopy roots were the same as belowground roots in their structure and anatomy, their capacity for forming symbiotic relationships, and their capacity for nutrient storage and transfer. If, by providing efficient nutrient transfer from epiphytes to host trees, canopy roots serve as a means of conserving nutrients within an ecosystem, then canopy rooting should occur on trees in geographically distant but environmentally similar ecosystems where high rainfall supports heavy loads of epiphytes.

In 1980, soon after research began in the temperate forest of Olympic Park, I journeyed to the cloud forests of Monteverde, Costa Rica, where epiphytes reach their greatest abundance and include the greatest number of species. Owned and administered by the Tropical Science Center in San José, the Monteverde Reserve protects approximately 10,000 acres

of virgin, mountainside forests. Here along the Central Divide in the Tilaran Mountains, at an altitude of about 5,000 feet, cloud-bearing trade winds sweep the peaks and valleys throughout the year, and fog envelops the mountain crests in thick, huddling mists. The forest is characterized by wet soils and trees with divided trunks, gnarled limbs, and leathery leaves. On the wet, windward slopes of the uppermost forest, where trees are so stunted that the forests are commonly known as elfin woodland, epiphytes grow in profusion. In addition to mosses, liverworts, and epiphytic lichens, a huge variety of higher plants grows epiphytically, clothing the wind-sculpted limbs with green and brown sleeves of living plants and decaying matter.

Aloft in the cloud forest canopy, I was surrounded by erect shrubs, lianas, vines, bromeliads, flowering herbs, cyclanths ("Panama hat" palms), and fragile orchids. Lifting mats of epiphytes as I had done in temperate forests, I found canopy roots emerging from the branches of these tropical trees. Host trees belonged to a diverse assemblage of species: *Ocotea* (family Lauraceae), *Xylosma* (Flacourtiaceae), *Didymopanax* (Araliaceae), and *Weinmannia* (Cunoniaceae).

In 1981 I expanded my research to the South Pacific, exploring the mountainous cloud forest of Papua New Guinea and the temperate rain forests of New Zealand, both Old World counterparts of the forests I had originally investigated. Again and again I encountered the same phenomenon. Ten species of tropical trees growing on Mount Missim (elevation 9,700 feet) near the Wau Ecology Institute in Morobe Province, Papua New Guinea, had root systems high in the canopy. While I was tree hopping in the *Podocarpus* forests of Pureora National Park, North Island, New Zealand, my checklist of canopy-rooting trees expanded to include *Grisilinia lucide*, *Meterosideros umbellata*, and *Podocarpus totara*. The evidence was mounting: Canopy rooting is not restricted to a single phylogenetic line—to trees that share common ancestors and evolutionary development—or to any specific ecosystem. Rather, it seems to be a generalized response wherever epiphytic growth generates a source of water- and nutrient-holding organic matter.

Biologically, epiphytes are commensals: they and their host trees live in close association but do not harm one another. Nonetheless, epiphytes do affect the nutritional status of their host trees, in a wide range of interactions.

In all cases, epiphytes gain the benefits of support within the canopy: higher lev of sunlight than on the dark forest fl and avoidance of possible competit from ground-dwelling herbs and moss But if we look at the relation between e phytes and their hosts on a continuum kind of gradient of coexistence, what e phytes offer their hosts in return for s port ranges from the extreme of para ism to a more positive mutualism.

The best example of the negative eff that epiphytes can have upon their host illustrated by the relationship between various epiphytic orchids and their h trees and shrubs in tropical citrus plan tions. In this case, strands of fungi link to orchid roots burrow directly into host tree's vascular system, robbing it

ts nutritional resources. The condition, known as epiphytosis, can have a debilitating effect on the tree canopies, causing oss of vigor and eventual death.

An indirectly negative effect of epiphytes upon their hosts has been described by David Benzing, professor of biology at Oberlin College, in his investigation of Floridian Spanish moss and live oak trees. Benzing coined the term "nutritional pirates" to describe epiphytes that intercept and seize atmospheric nutrients before they become available to their hosts. Crown-dwelling epiphytes are more favorably positioned in the canopy and physiologically better equipped than their hosts to exploit the limited supply of nutrients borne in dust and rainfall. Ultimately this pirating can result in host decline: heavily infested oaks gradually put forth fewer and fewer leaves and grow more slowly.

Nutritional neutrality is typified by the moderate moss loads found on old-growth conifers in the Pacific Northwest. Epiphytic mosses inhabit the inner portion of the canopy where they exert minimal mechanical stress and where light levels are too low to support host tree foliage. Since the mosses grow only in moderation, their effect upon the availability of airborne nutrients is negligible.

An example of an indirectly positive effect of epiphytes on the nutritional conditions of their hosts has been documented in a study conducted by Larry Pike and George Carroll, professors of biology at the University of Oregon. In this study, researchers computed nitrogen input of nitrogen-fixing lichens on old-growth Douglas firs in the temperate forests of Oregon. They found that epiphytes indirectly add one to three pounds per acre per year of nitrogen to the ecosystem through fixation and subsequent decomposition. This contribution is described as indirectly beneficial to host trees since nutrients are made available to saplings, seedlings, and other understory vegetation as well.

Tropical rain forest epiphytes were also described as indirect nutritional contributors to the canopy ecosystem. Richard Forman, then a professor of biology at Rutgers University, estimated a nitrogen input of one to seven pounds per acre per

A temperate rain forest such as this one on Washington's Olympic Peninsula may support as much as 6,000 pounds (dry weight) of epiphytes per acre.
Harald Sund

year from lichens in a Colombian rain forest, as much nitrogen as enters the system through rainfall.

The epiphyte–host tree relationship shifts even further toward mutuality when canopy rooting is considered. In this instance, the host tree, which provides support for epiphytic growth, gains direct access to accumulations of organic matter and decomposed mineral elements *before* the nutrients become available to neighboring trees and vegetation. A mutually beneficial association seems to prevail, one in which a direct benefit is conferred upon the host tree through access to epiphytic nutrients and to the epiphytes through support and a suitable surface on which to grow and reproduce.

When I first contemplated epiphyte research, I encountered some skepticism in forestry and biology circles. Swinging through trees with special rock-climbing apparatus—fancy Tarzan gear as some called it—seemed too exotic or perhaps too much fun for serious scientific research. There were, after all, plenty of unsettled questions about plant life on the forest floor. Epiphytes were considered interesting from a strictly botanical point of view but were not thought to be particularly relevant to fundamental ecosystem-level processes such as nutrient cycling. Apparently this treetop community of epiphytes has a greater impact on canopy ecology than previously suspected.

Whether epiphytes and their host trees coevolved for the express purpose of mutual aid remains an open question. Their association, examined from a different perspective, could as easily be interpreted as competitive, with host trees "snatching back" the nutrients that otherwise would have been theirs had epiphytes not intercepted them first.

Whatever the driving force behind these interactions, canopy rooting tightens the link between two diverse elements in a complex forest by offering trees quick and direct access to nutrients. And epiphytes, the often tiny plants that seem to thrive on air alone, can play a significant part in the mechanism of nutrient conservation that makes forests so good at holding on to their limited supply of nutrients. □

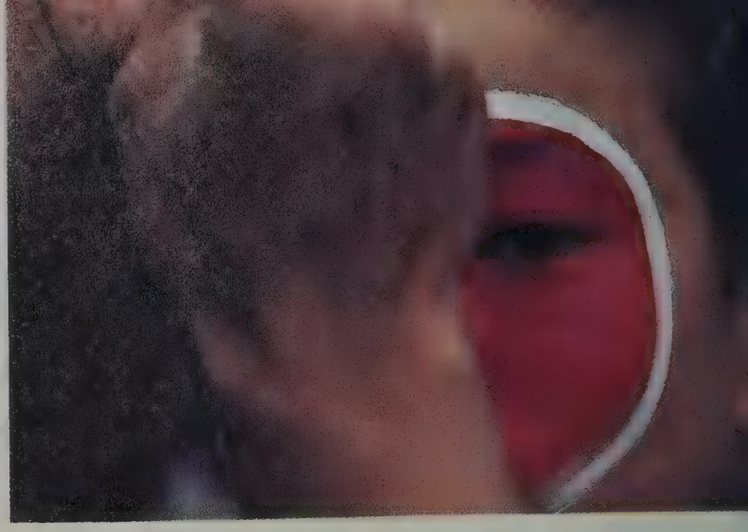
Welcome to the Year of the Ox!

For two weeks in January or February, all work comes to a halt as Chinese villagers celebrate the New Year

Photographs by Richard Gordon

A young actor from a semiprofessional opera company peeks out from behind a curtain. The troupe performs on outdoor stages in villages throughout Shaanxi Province.



Dressed as a pig, a boy on stilts, above, sets off giggles among this group of children, who recognize Pigsy, a character from Journey to the West, *one of the best-loved classics of Chinese literature. Pigsy is a former deity who intended to come to earth as a man, but he did something wrong and became a pig instead.*

A young boy, left, has a vivid red circle painted on his face, identifying him to all as the Monkey King, another character from Journey to the West. *The Monkey King possesses great magical powers and can see through the disguises of even the cleverest of demons and monsters.*

Villagers gather to watch the traditional Lion Dance, below. Inside each costume, two men coordinate their movements to manipulate the lion, as it blinks its eyes, snaps its mouth open and shut, and chases after a ball handled by a costumed man—all to the great amusement of the crowd.

A small boy stands behind the makeshift wall and gate of a newly constructed house. On the gateposts are New Year's couplets, which are put up by every family. Traditional couplets carry auspicious words about good weather, healthy children, and long life. The couplet here reads, "Sweet, sweet, sweet. Life is more and more sweet. Beautiful, beautiful, beautiful. The days are more and more beautiful."

As part of the two-week celebration, villagers build giant swings. This ancient custom has been mentioned in poetry and folktales for more than a thousand years, and stone rubbings of giant swings have been found that date back to the Han dynasty (202 B.C.–A.D. 220). During the festivities, unmarried men and women occasionally use the swings together, an activity considered very risqué.

Elaborately costumed young girls, above, are carried on poles in a procession through the streets of a village. Although they appear to be standing, the girls are strapped into small metal seats attached to the top of the pole. Their adult-size opera costumes include false legs and tiny (false) bound feet.

In the countryside, free movies are shown on outdoor screens about once a week. Opera, however, remains the favorite of elderly people, who tend to find the movies too daring. At righ a group waits patiently at the foot of an outdoor stage for an opera performance to begin.

A stilt dancer dressed as an elephant rider proceeds down a crowded street. The dancer may be impersonating one of the Eight Immortals, characters from a legend.

The custom of carrying young girls, about four to six years old, on poles in a parade is called kang zhuang *(literally, to shoulder a costumed person).*

band of stilt dancers, left, parades down a village street. close inspection of the dancers reveals several female personators in the group. Villagers feel that female personators have more freedom to flirt and dance in a anner that would not be appropriate for a woman.

The young girls, below, are riding in a decorated wagon being pulled by a tractor—part of a procession through the village streets. Sunglasses are a fashion fad in Shaanxi Province and are considered a stylish necessity for all special occasions—especially at New Year's, weddings, and performances.

Th

Rhesus monkey populations have declined seriously in Nepal and northern India. Many people no longer hold monkeys sacred, and some farmers trap them or drive them away. As a result, monkeys find refuge in public places, such as this Buddhist temple area in Kathmandu, Nepal.

Mark N. Boulton, Bruce Coleman Inc.

Rhesus Monkey's Fall from Grace

There is little place left in modern India for a sacred species

by Charles Southwick and M. Farooq Siddiqi

Admired and worshiped by some, cursed by others, rhesus monkeys fill a complicated ecological and cultural niche in India and Nepal. Orthodox Hindus consider monkeys sacred animals, to be revered and protected. This reverence stems partly from the role of the monkey god, Hanuman, in the *Ramayana*. In that classic Hindu epic, Sita, the beloved wife of Rama (the reincarnation of Lord Vishnu) is kidnapped by the forces of evil. Hanuman learns she is being held on the island of Lankah (modern Sri Lanka). But in order to get onto the island, a rescue party will have to cross the water. So Hanuman calls on the monkeys to gather in southern India and build a bridge. Hanuman, Rama, and their followers walk across that bridge, and after fierce fighting, rescue Sita. According to the legend, this represented the victory of good over evil. Today, many Hindu temples are dedicated to the monkey god.

Hanuman is usually depicted as a langur, a long-tailed monkey with a black face. But over the years, he has come to stand for all monkeys, including the rhesus, and all of them have enjoyed the privileges of deification to some extent. The rhesus ranges widely across India, but the populated regions with the greatest numbers of monkeys are often those connected in some way with the legend of Hanuman. Indeed, the religious associations that Indian people have with monkeys are the main reason these primates have been tolerated and protected.

In the Western world, the rhesus monkey has another sort of distinction, stemming from its role in biomedical and behavioral research. For more than fifty years, it has been a mainstay for scientists exploring ways to improve human health—mainly because of its physiological and immunological similarity to humans. The Rh factor in our blood was named after a similar protein found in the blood of the rhesus monkey. This primate was an experimental model for polio and hepatitis vaccines and has been used widely in almost every field of medical research. As a result of tests on pregnant rhesus monkeys, the tranquilizer thalidomide—which had been tested on mice, rats, and rabbits without incident and was being used with tragic consequences by pregnant women in Europe—was banned in the United States. All of this research required monkeys, and in the late 1950s, India was exporting more than 100,000 of them each year to Europe and the United States.

The rhesus thus had a contradictory sort of fame in the 1950s—worshiped on one side of the world, it was used for laboratory research and pharmaceutical testing on the other. But for those of us who wanted to study this fascinating primate and understand its place in nature, there was little to go on. We knew only a few facts—for example, that the rhesus was one of twelve macaque species and that it ranged over more than 5,000 miles of Asia, from Afghanistan in the west, across India and Nepal, to Bangladesh, Burma, and parts of Indochina. The most widely distributed primate, it once lived as far east as Hong Kong and is still found in the forests of Kowloon, a mainland peninsula of that city. Formerly, its northern limit was Peking. Now it is rare in China and has disappeared from many other parts of its eastern range. But the center of the rhesus monkey's population, and the place where it could be found in greatest numbers, was, and is, northern India.

We also knew that the rhesus was versatile ecologically, for it lived in cool Himalayan forests as high as 12,000 feet, in the hot lowlands of the Rajasthan Desert, and in the tropical mangrove swamps of the Sundarbans in Bengal. We knew that it had, at some point, developed a commensal relationship with human populations, receiving food and other benefits from that association. In India and elsewhere, the rhesus lived with people—in agricultural areas, villages, towns, temples, railway stations, and even major cities. In the crowded landscape of India, the rhesus seemed to be a survivor—the most intense human commensal of all primates.

But in the late 1950s no data were available on such basic matters as the animal's habitat distribution, population densities, group sizes, sex and age structures, breeding habits, or social organization. We knew very little about its food habits. As

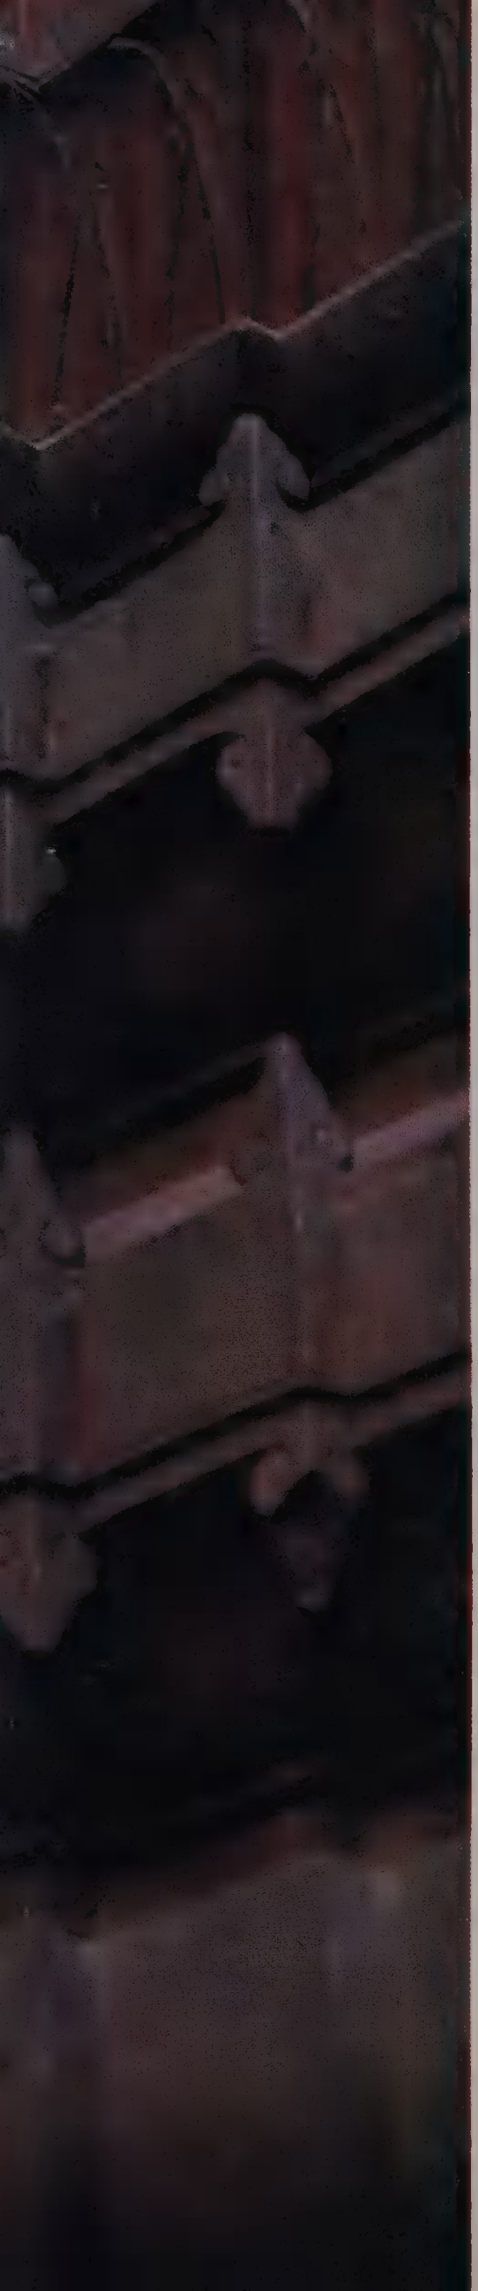
late as 1960, we didn't know whether rhesus monkeys actually had a mating season or bred throughout the year. In captivity, reproduction occurs throughout the year, but we soon learned in our fieldwork that rhesus have a definite breeding season from September to January.

There were other questions as well, perhaps even more pressing ones, raised by the human relationship to monkeys. How many rhesus monkeys actually lived in northern India? What were their population trends? How were the populations organized, ecologically and socially? What did contemporary citizens of India think of the export of rhesus? And could the monkey populations continue to sustain modern science with a harvest of 100,000 or more individuals per year?

When we began our study in 1959, we planned a year of fieldwork. Soon after our first field season, we realized that we needed three to four years. Now, as we complete our twenty-fifth year of fieldwork, many topics still remain to be investigated. But one alarming fact has emerged: the rhesus monkey population of northern India has seriously declined since 1959. Some people may attribute the loss to the export of rhesus monkeys. But we learned early in our studies that the exploitation of the monkeys was only part of the circumstances affecting them. Their situation in India is a complicated and changing one, and to understand it, we had to understand something of the changing identity of India herself.

Our first task was to find out how many monkeys there were. When we began our studies, government officials, scientists, and naturalists felt the rhesus population numbered in the millions—that it was so large that the levels of export in the 1950s and 1960s were not having any impact. Jim Corbett, one of India's respected naturalists, estimated the monkey population of Uttar Pradesh, the north-central province occupying much of the Gangetic basin, at "not less than ten million." Some estimates ran as high as twenty million.

In 1959, we began three kinds of studies. The first was an extensive population survey throughout northern India, the second a more intensive study of one popula-



Many rhesus monkeys in the central Indian city of Varanasi (Benares) live around Durga Temple, known locally as the monkey temple. People feed rhesus as a tribute to Hanuman, the monkey god, who symbolizes the triumph of good over evil.
Rajesh Bedi

tion in Aligarh District, eighty miles southeast of New Delhi, and the third a behavioral study of groups of rhesus monkeys living near monkey temples in the city of Aligarh.

How does one count monkeys in the diverse landscape of northern India? We began with seven different types of field surveys, designed to cover all habitats systematically. We used all available means of transportation—automobiles, bicycles, trains, and most often, our own feet—to crisscross the landscape as carefully as possible. In our first nine months, we logged more than 18,000 miles, talking with local people and thoroughly inspecting 280 villages, 30 towns, and 15 cities in northern India. We censused more than 200 Hindu temples and more than 440 railroad stations, and we combed 6,400 acres of forestland in the Himalayan foothills.

From these efforts we learned that the popular notion of how many monkeys lived in India was greatly exaggerated. Our survey indicated that rhesus monkeys in Uttar Pradesh numbered 800,000 to a million, or about 10 percent of what we had been told. And we further estimated that 88 percent of this population lived near human settlements—villages, towns, cities, roadsides, canal banks, or temples. Only 12 percent lived in the forested areas. Almost everywhere we went, we found that local people overestimated the number of monkeys living near them. Fifty monkeys, by virtue of their visibility, boldness, and activity, could create the impression of several hundred.

Another factor that impressed us was the patchiness of rhesus distribution. In some areas, like the sacred towns of Ayodhya and Faizabad, there were many groups, sometimes as many as seventeen in just five miles along the road. In other places we could ride or walk for a hundred miles and find only one or two groups, sometimes none. "There used to be monkeys here," local people told us, "but not anymore."

But what most shocked us in those initial forays was the distorted age range of the monkeys. There were conspicuous shortages in one age group—monkeys one to two and one-half years old. Juveniles in this category, past weaning but sexually immature, should make up at least 25 percent of a numerically stable population. Instead, they were only 5 percent of the total population. Monkeys in this age group, particularly those about eighteen months old, were in greatest demand for research. This meant that trapping for export was making a serious dent in the population. Where monkeys were less likely to be trapped—in temples and protected forests—the population's age distribution was normal.

We also found that Indian villagers were deeply ambivalent about the rhesus monkey. Although they still professed to respect monkeys for traditional reasons, they considered the rhesus a pest—particularly in agricultural areas where the monkeys often pilfered crops. Many villagers asked us to trap and take the monkeys away. Unwilling to kill them, people nonetheless tried to drive them off or break up groups. The monkey's status in India had obviously changed. When we explored the Terai, that band of forest running along the Himalayan foothills, we saw another sign of the times. India's greatest wildlife areas, the forests of the Terai were being invaded to make room for agriculture and grazing land. This development inevitably had to affect rhesus monkeys dependent on forest habitat.

What we were seeing, of course, were the beginnings of India's change to a more modern, industrialized, and growth-oriented society. During our twenty-five years in India, the human population doubled from fewer than 350 million people to more than 700 million. Each year we saw increasing evidence of conflict between traditional beliefs and the realities of survival. We were particularly struck by this in small villages, where local people grew their own crops and were entirely dependent on local food production.

Rhesus monkeys consume virtually all vegetable foods that humans eat. They raid crops and rob food stores at every opportunity. They love mangoes, papayas, bananas, sugar cane, rice, grams (leguminous beans, somewhat like soybeans), peanuts, wheat, millet, and most vegetables.

A triumvirate of monkeys holds court on a rooftop in Agra. The sign is an advertisement for a writing pen. Urban monkey populations in northern India have declined less than village populations, mainly because they don't threaten people's livelihoods, and thus are tolerated. But even in rural settings, some people have returned to a more traditional respect for the rhesus. At right, a knife peddler stops to feed a roadside group in Tughlaqabad.

Doranne Jacobson

With food supplies a constant problem, the average villager simply cannot afford to have a group of monkeys ready to pounce on his crops. Small children and elderly people are regularly employed as *chowkidors*, or guards, to protect the crops against the depredations of monkeys. Traditional Hindus believe that monkeys have a "right" to whatever food they need, but many of the contemporary villagers we spoke to are more pragmatic. They still believe in the legends of the *Ramayana*, but they no longer accept the idea that they can do nothing about poverty and hunger, that they are powerless to act against the monkeys. Without rejecting their religion, they are modifying some of its teachings in practice. In the last two or three years, there has been a noticeable resurgence of classical Hinduism in India, and more people are once again feeding monkeys along roadsides and in temples and parks.

Another major influence upon the rhesus monkey has been habitat destruction of the sort we witnessed in the Terai. Since the early 1950s more than seven million acres of Indian forests have been cut. Much of this land has been taken over by agribusiness, and small farmers have had to sell to larger landholders. Now many farms are fifty or a hundred acres. Corporate managers often show little tolerance for rhesus monkeys; they certainly don't consider them gods, and the traditions of Hinduism are less of a constraint for them.

Reforestation efforts are under way in India, but most plantings are of single-species stands, especially eucalyptus species, which are relatively worthless as wildlife habitat in comparison with the rich mixed-species forests being cut. Initially, this practice drove rhesus monkeys to the roadsides, where some fringes of the old forest still remained and where, outside of villages and fields, they were less likely to be bothered by people. More recently, even these marginal areas have been cut for lumber and firewood, and many roadside stands of fine banyan, pipal, neem, jamun, and mango trees are gone.

During our first year of fieldwork, long before we had a clear picture of these other factors, but armed with what we felt was a fairly accurate idea of rhesus population trends, we predicted the number of rhesus monkeys in India was declining. Since 1960 we've had the opportunity to test these predictions several times, first after five years, in 1964 and 1965, and again after twenty years, in 1979 and 1980. We retraced our early work over a broad expanse of northern India as precisely as possible, using the same field methods, the same routes and study areas, and basically the same field teams. Unfortunately, the data supported our early predictions. There has been a serious decline with relatively few local exceptions.

Between our first and second surveys, roadside groups of monkeys in northern India declined 26 percent; by 1980, that decline deepened to 77 percent. In other words, three-fourths of the rhesus living in roadside habitats disappeared over the twenty years.

Along canal banks, which are less disturbed by human traffic and which often have ideal habitat, a similar situation prevailed. When we repeated a survey of more than 180 miles in this habitat, we found that 76 percent of the groups of rhesus monkeys had disappeared.

In village habitats, the loss was alarming. In our 1959–60 study, 44 of the 280 villages we visited had resident rhesus monkey groups. Twenty years later, only 5 of those villages had monkeys. To make sure that the missing groups hadn't simply moved to other villages, we surveyed an additional 245 villages and found no rhesus in them. Total numbers of village rhesus had declined 94 percent.

Our intensive study of monkeys in Aligarh District gave us a more detailed picture of what was happening in rural areas. Aligarh is typical agricultural land of the western Gangetic basin. It is flat, intensely cultivated with wheat, gram, sugar cane, millet, and other crops; moderately well-watered with canals from the Ganga River; and densely populated by approximately 500 people per square kilometer in the rural areas. In this district, we selected seventeen groups of rhesus monkeys in typical habitats, including temples. The groups varied in size from six to forty-nine monkeys, with an average of twenty per group. A typical group consisted of four adult males, eight females, six infants under one year of age, and two juveniles aged one to three. These groups occupied roadsides, villages, schoolyards, canal banks, and forest patches. With continued support from the National Institutes of Health, we have censused these groups three times annually: in March and April, just before the birth season, to obtain the

Rod Johnson

lowest population count of the year; in July and August, just after the birth season, to record all births and the highest population of the year; and in October and November, just after the monsoon, to get a record of early infant mortality and monsoon deaths.

In 1962, after three years of moderate increase, the population began an erratic decline, dropping from a high of 403 monkeys in twenty-two groups to a low of 163 monkeys in only ten groups by March of 1970. Twelve of twenty-two groups disappeared entirely. In some, every individual had been trapped; other groups had been broken up or declined slowly by attrition. There were no significant animal predators—but both dogs and people harassed the monkeys. We saw one instance in a canal bank group where a dog snatched and killed a young infant. Boys and men often threw sticks and stones at monkeys and occasionally shot them with powerful slings.

The picture was somewhat better in towns. We defined towns as places with more than 2,000 inhabitants, with markets, temples, parks, and other public areas. Of thirty towns that we surveyed, twenty-one had rhesus groups in the early study, and sixteen had them twenty years later—a decline of only 24 percent.

Why would rhesus in towns lose only 24 percent and those in villages so much more? In villages, the monkeys are a threat to survival. But in towns, most people are not farmers. They buy food at the market, and rhesus monkeys in the town's parks or shrines are not an immediate threat to them. Townspeople enjoy the monkeys—parents and grandparents often bring their children to feed them. Sometimes it's a religious ritual, but often it is like going to an open zoo whose borders correspond roughly to the town's public areas. The ever adaptable rhesus scrounges and begs, and people supply the food. In these settings, the rhesus is a little like the pigeon in big cities, except rhesus monkeys are much more animated. They are equally at home on the ground, in trees, and all over buildings. They love to dive and swim in ponds or lakes. They chase, beg, quarrel, play, and occasionally cause a minor furor when one of them bites somebody. Rhesus generally inspire that ambivalent mix of affection and distaste one feels for an endearing but mischievous pest.

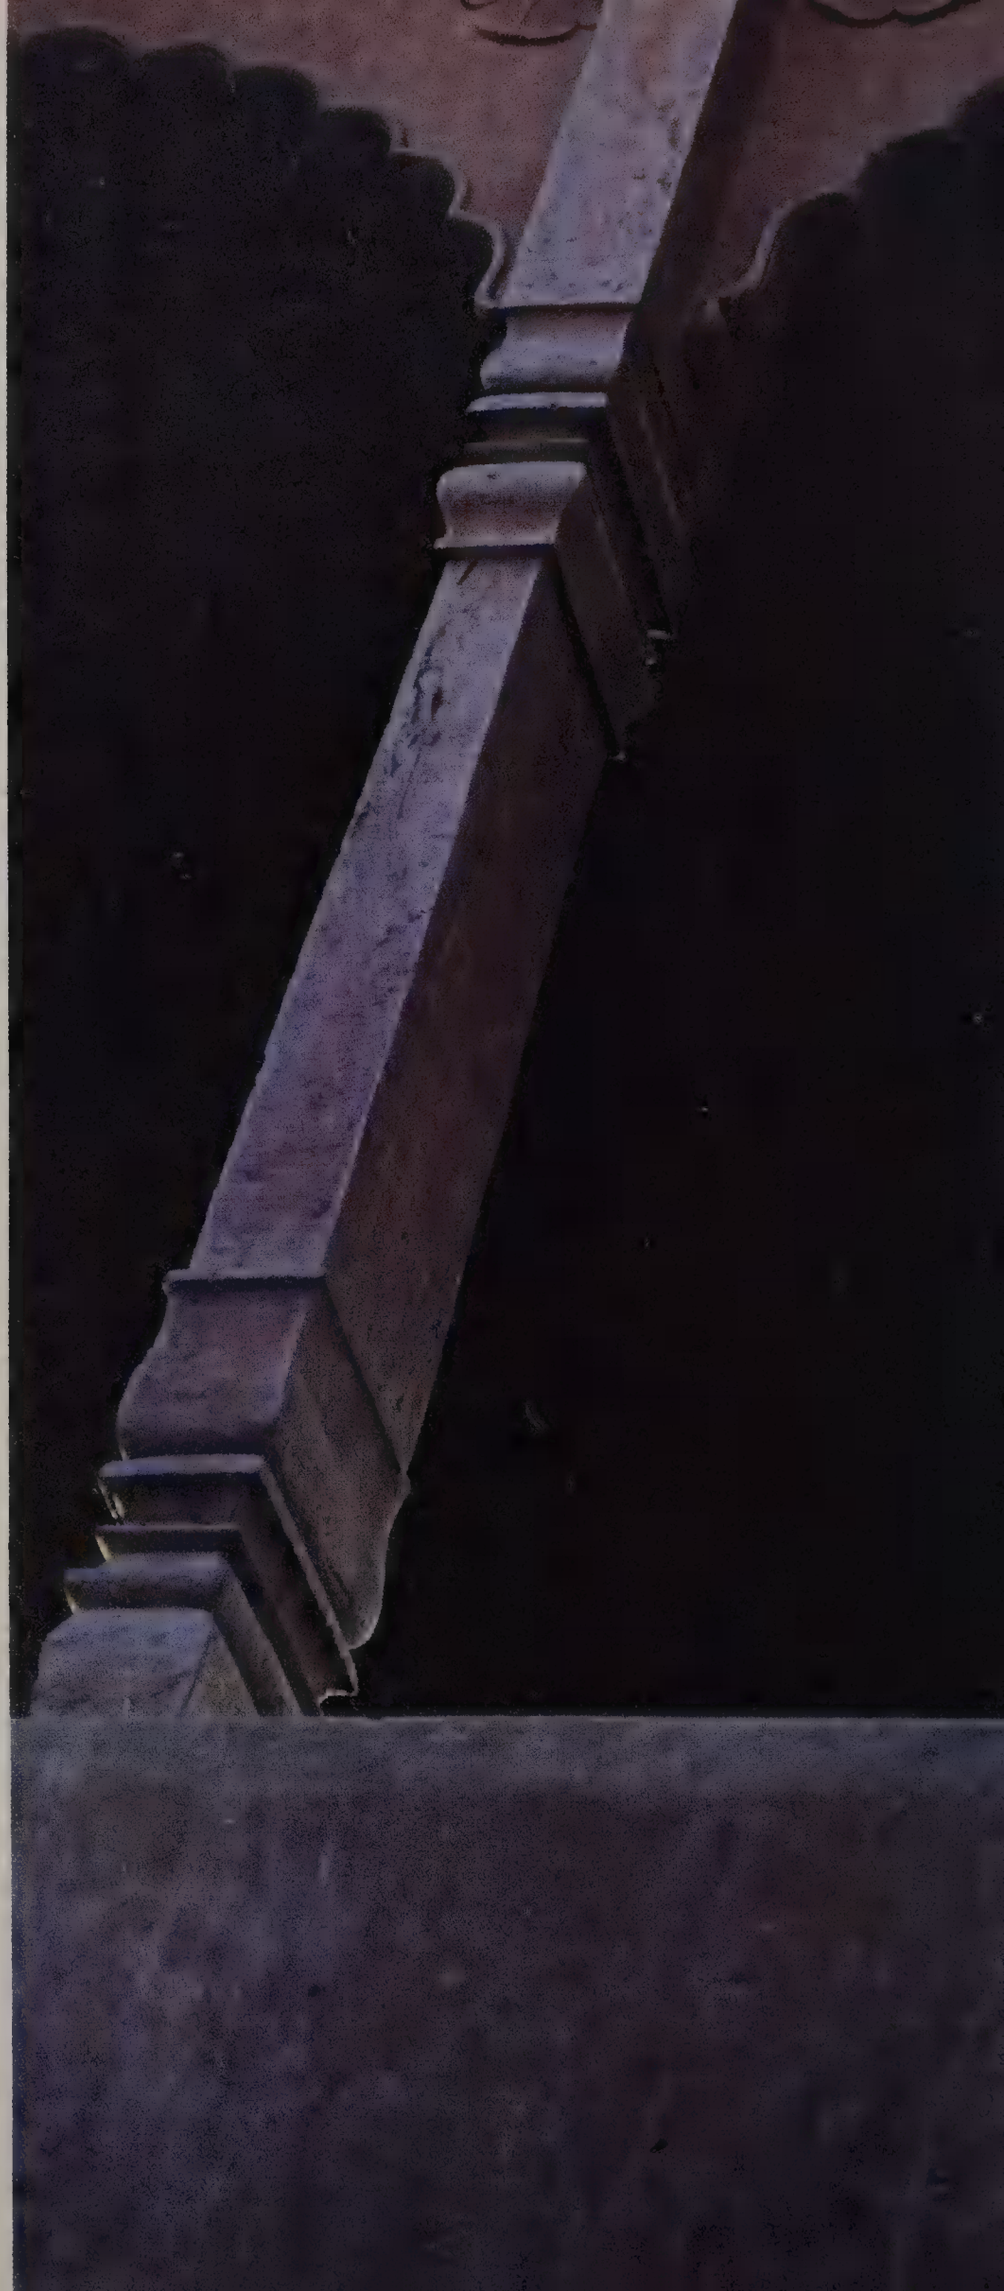
Another habitat we have tracked for rhesus populations over these years has been the forests of the Terai. Our figures there are less precise, but those we have from Corbett National Park showed rhesus populations to be stable, with less than one group (0.7) per square mile. This stability is encouraging, but Corbett is one of only a few national parks inhabited by the rhesus monkey. Most of India's forests are not so well protected.

When we put all our figures together, we estimate that since 1960, the rhesus population of northern India has declined between 80 and 90 percent. Based upon our initial population estimates from 1960, we now estimate the population of Uttar Pradesh to be 80,000 to 100,000 monkeys. We also conclude that the rhesus population in all of India is now on the order of 160,000 to 200,000 monkeys—certainly a dramatic difference from the 5 to 10 million, or even 20 million, animals thought to inhabit Uttar Pradesh alone in the 1950s.

In the late 1970s, the Indian government became concerned about its dwindling primate populations. In April 1978, the government placed a total ban on rhesus export. Export had declined significantly to only 18,000 rhesus in 1977–78, but officials felt even this was too serious a loss in concert with other ecological and social forces acting against the monkeys of India. Some trapping is still permitted within India to obtain monkeys for biomedical research, but trapping for export was stopped in 1978.

A monkey family takes time to groom and nap in Varanasi. Where monkeys are protected, they show high birthrates—one study in Aligarh District recorded a rate of 90.3 percent—and they can increase their numbers rapidly.

Rajesh Bedi



In 1977, just before the export ban, the government launched a nationwide survey of primate populations—a major mobilization of scientific expertise covering not only rhesus monkeys but also langurs, bonnet macaques, lion-tailed macaques, and Hoolock gibbons.

The National Primate Survey of India, under the leadership of K.K. Tuvari, R.P. Mubherjee, and G.U. Kurup, took twenty-one professional scientists and more than thirty-five fieldworkers five years to finish. Field teams undertook one of the most thorough national coverages of primate populations ever attempted—they surveyed virtually all of India's twenty-five provinces. They also found that Uttar Pradesh had the greatest concentration of rhesus in India. More extensive and detailed than our own, the national survey estimated that the rhesus population of India was only 183,000 individuals in 1983. One of the world's greatest nonhuman primate populations was now a fraction of its former self.

In this discouraging situation, there are some encouraging exceptions. One of the most striking to us was the case of a small group of monkeys living in a grove of trees surrounding a rural schoolyard in Aligarh District. This place, known as Chhatarido-Raha, was rigorously protected by the schoolmaster and two elderly guards. They permitted no trapping or harassment of the monkeys, though the monkeys were on their own once they wandered out of the schoolyard compound and its sheltering trees. None of the other groups in our Aligarh sample had even this degree of protection. During the eight years from 1962 to 1970, the Chhatari rhesus population actually increased from forty-nine to seventy-four individuals. To us, this was a dramatic example of how important the human factor was. The Chhatari habitat was not any better than many other sites in Aligarh District; in fact, it was sparser in cover and space. The difference was the protection afforded by local people.

Throughout most of the 1970s, the Chhatari population continued to thrive, while the remainder of the Aligarh population declined. By the summer of 1978, Chhatari reached a population of 149

People and monkeys mingle on the steps of a Hindu temple. In Indian cities, rhesus are often ubiquitous, much like pigeons in New York or London, and they inspire the same mixture of affection and distaste.

Thomas Richie

monkeys, whereas the rest of Aligarh District had only 87. Throughout these years of study, the Chhatari monkeys maintained a remarkably high (90.3 percent) birthrate, and a low infant-mortality rate. Juvenile loss was moderate (31.5 percent) and adult mortality was also low (only 12.5 percent per year).

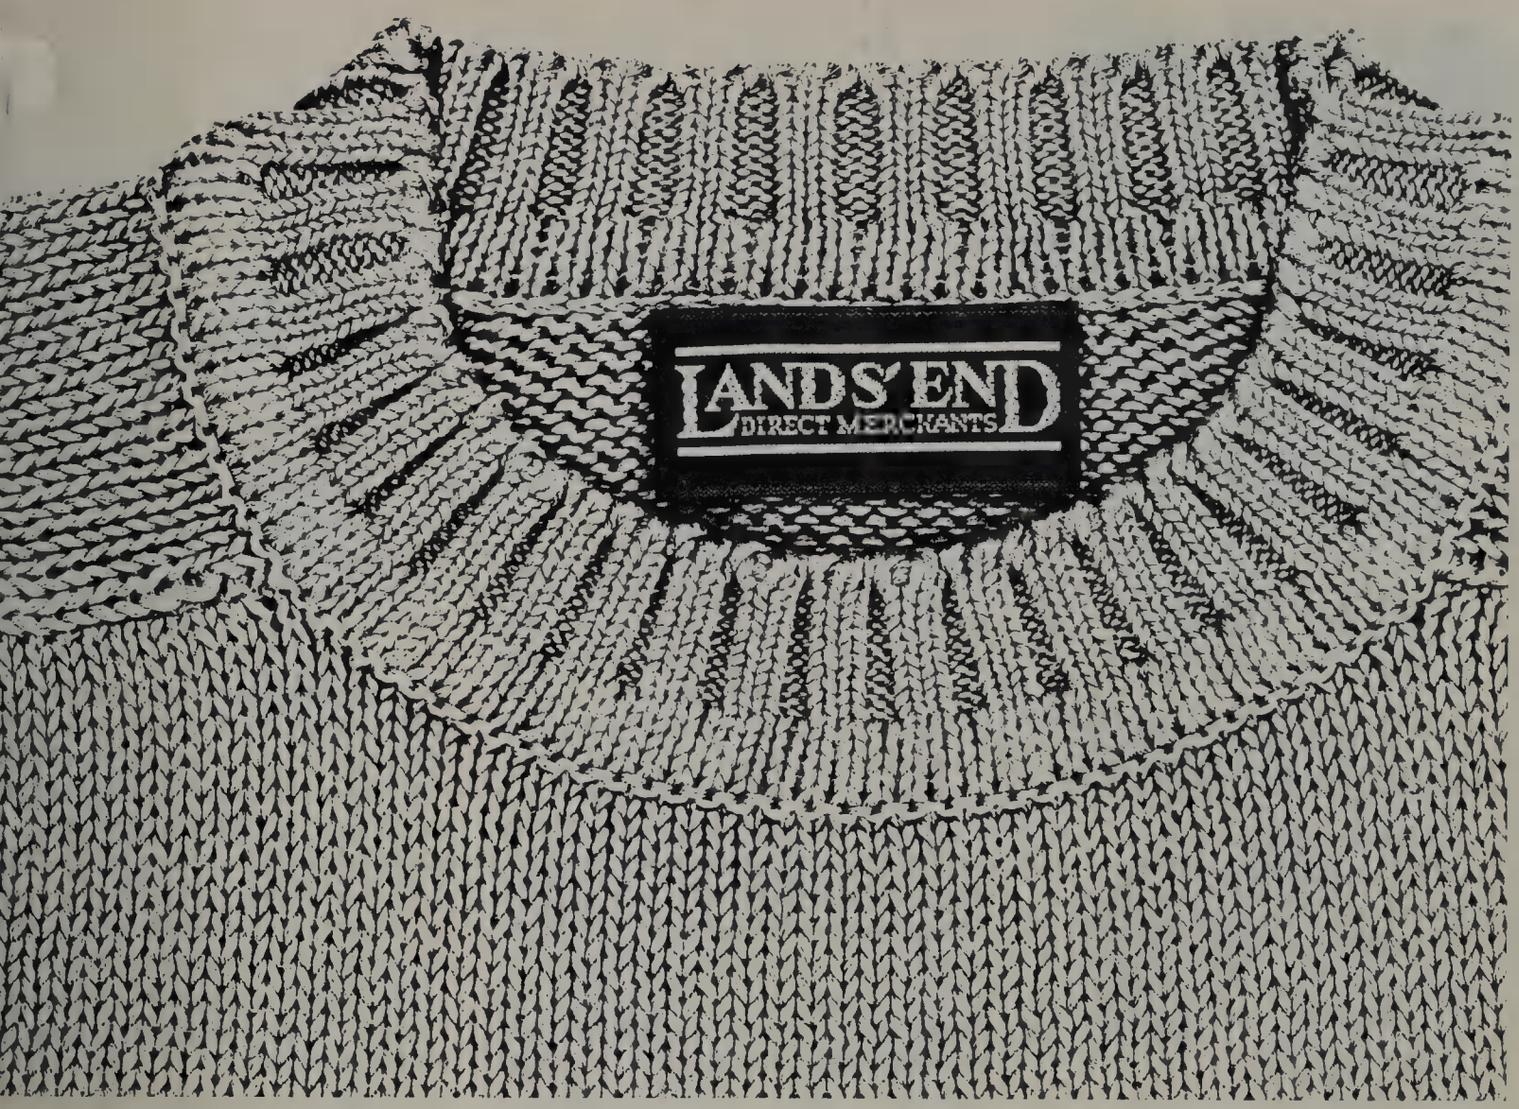
The unprotected rhesus monkeys of Aligarh had a lower birthrate (76 percent) and higher mortality rates in all age classes (18 percent in infants, 54 percent in juveniles, and 17 percent in adults). The impact of human attitudes and behavior on a nonhuman primate population was unmistakable. Rod Johnson of the University of Colorado has been doing a detailed behavioral study of rhesus mother–infant relationships in an attempt to learn more about the secret of Chhatari's success.

There are other locations in northern India where the local rhesus population is thriving. In the archeological site of Tughlaqabad on the southern outskirts of New Delhi, Iqbal Malik has studied a population of rhesus monkeys that has increased markedly in recent years. This is a large protected area of two square miles, surrounding the ruins of a fourteenth-century city, and it also contains several hundred acres of young forest plantation. With complete protection and an improving habitat, the Tughlaqabad groups have increased from two to five and their total population has more than doubled, from 120 to 286, in four years.

We have also censused rhesus groups in Banda District of southern Uttar Pradesh, where a local population on a sacred hill increased from five groups with 109 monkeys in 1960 to eleven groups totaling 267 monkeys in 1980. P.K. Seth, an anthropologist at the University of Delhi, found nine other rhesus groups throughout Rajasthan, Haryana, and western Uttar Pradesh that increased 66 percent between 1975 and 1980, with a total population change from 400 individuals in 1975 to 665 by 1980.

Can these small increases constitute a major change in the status of rhesus monkeys in contemporary India? The evidence is secure that rhesus monkeys can increase rapidly in number when protected and supplied with adequate habitat. Since increased numbers of monkeys in some areas may create agricultural problems, one solution would be to relocate subgroups from very large groups to unoccupied habitats. We have recently undertaken a pilot study of this type by relocating twenty monkeys from a large group of more than a hundred that were doing serious damage in a mango grove. We moved them to an unoccupied canal bank area in September 1983, and so far these monkeys are doing well. We had to feed them for several months to keep them in their new location, but this supplemental feeding has now been stopped and they seem fully adjusted to their new home range. They are producing well.

Fortunately, India's agricultural outp has increased greatly throughout t 1970s, and we hope that this will mitiga some of the conflict between primates a people, between India's critical need food and the desire of her people to c serve their rich store of wildlife, amo which primates have such an importa role. We do not believe the rhesus monk population of India can ever be what once was—and certainly not what peo imagined it to be—but we have reason hope that it is now recovering from ma years of decline.



Cotton. The most versatile and comfortable fibre in the world. Naturally.

(And no one offers you more all-cotton items than Lands' End)

an you imagine life on this planet without cotton? It feels so good and esh and airy. And without the slightest oblem it can look lustrous and silky st as easily as it looks fresh and crisp.

Here at Lands' End we hold cotton the highest esteem. We've learned to preciate how versatile it is. How well takes and holds colors true to the ectrum. And how beautifully it sponds to fine design.

Giving Nature a hand with raw cotton.

u don't set out to improve on Nature htly. So, at Lands' End, when we plan new cotton garment, we start with e best cotton there is—100% cotton, mbed and, where appropriate, ercerized. Mercerizing involves eating the yarn or the fabric to give it softer hand—a softer feel to the uch, that is. This treatment lets the bric retain richer dye colors and put fierce resistance to shrinkage.

This Spring, once again, cotton is king.

u'll note in our catalogs that here and there we feature items made of other fabrics. But far and away, it is cotton which reigns as king. Whether it's our cotton twills, cotton shirtings, or cotton in a variety of sophisticated knits, Lands' End offers cotton in so many products reciting them almost adds up to a chant.

You'll find cotton jeans, knit shirts, and a range of cotton ties. And cotton shirts, cotton sweaters, cotton trousers, cotton skirts. And don't miss our sleek trim cotton turtlenecks, and our rugged cotton shorts, stretch or otherwise. Cotton sweats are ideal for you who're into Spring training. And cotton socks and dresses need no explaining. But how often do you think of cotton in luggage? Yet it's a mainstay fibre throughout our many Lands' Ends-made soft luggage lines.

Yes, we have cotton by the catalog-full.

We say it advisedly because it's true. *No one offers more all-cotton items than Lands' End.* At prices throughout which constitute value. To check us out order our latest catalog today. By mail, via the coupon below. By phone, on our toll-free 800 number(800-356-4444), attended 24 hours a day.

And don't forget, 100% cotton stays new looking whether you hand wash it, have it dry cleaned, or beat it against a rock. We guarantee it the way we guarantee every other item we offer. Unconditionally.
As in GUARANTEED. PERIOD.

Please send free catalog.

The Hall That Mead Bu

The Margaret Mead Hall of Pacific Peoples, a new permanent exhibition hall, opened on December 14 at the American Museum of Natural History. In 1971, Mead herself summed up the importance of creating an exhibition for the Museum: "Anthropologists do collect as part of their work, looking ahead to a time when they will make an exhibition. This is a very different matter from organizing an exhibit from a random assembly of spears, shields, baskets, and bowls. . . .When you make your own collection, you know why you chose each piece, just how it was used, and often who made it."

The hall presents the cultures of the peoples of the Pacific islands. Some 1,500 artifacts illustrate such cultural activities as the puppet theater of Bali, the kava drinking ceremony of the Samoan people, and the Trobriand Islanders' kula exchange system, which uses shells and necklaces to reinforce trade relationships. Other displays show the kinds and uses money; the use of coconuts and betel n the types and uses of weapons; the cheology, ethnology, and physical thropology of the Pacific; and the effe of contact with Western culture.

The earliest piece displayed in the is an archaic kris from Java. Later a facts are post-World War II. Some pieces displayed in the hall were collec by Mead. Among the more unusual a facts are a Maori feast bowl used to se dog flesh; a full-sized, intricately car Maori storehouse; a navigation chart u by the people of Micronesia; and a twe foot-high cast of an Easter Island hea

The hall also features an entire case voted to the art of the Sepik River Ba Artifacts range from the naturali (birds, crocodiles) to the highly abstr (spirit masks). The works are known their bold, colorful forms.

Mead wrote that the hall should ref

At the American Museum

New Magazine for Children

Faces, a new magazine for children eight to fourteen years old, is being published in cooperation with the American Museum of Natural History. It will contain articles, games, puzzles, and stories about world cultures, anthropology, and archeology.

Each issue will have a special theme; among them will be dragons, Indian myths and legends, keeping warm, and African gold.

Faces is published by Cobblestone Publishing in cooperation with the Museum. Subscriptions are $13.95 for members of the Museum, $16.50 for nonmembers. To subscribe, please make your check payable to Cobblestone Publishing and send it to: *Faces* Magazine, 20 Grove Street, Peterborough, NH 03458. If the subscription is a gift, indicate whether you want a gift card to be sent in your name.

Return of the Osprey

The Membership Office is presenting *Return of the Osprey*, a film by Michael Male and Judy Fieth. Their close-up view of several osprey families on Long Island nesting, raising young, hunting, and courting will be shown on Thursday, February 14, at 7:30 P.M. in the Auditorium; it free and open only to members. For tick information call (212) 873-1327.

Black History Month

February is Black History Month at t Museum, and a number of events ha been planned to celebrate contributio by blacks to American and world cultur

People Center Events: Every weeken the Leonhardt People Center will featu free lecture-demonstrations, music, a dance from 1:00 to 4:30 P.M. Programs i clude a demonstration of African a American weaving styles and an explor tion of black music.

Kaufmann Theater: On Sunday, Fe ruary 10, there will be two performanc of African festival dances at 2:00 and 4: P.M. On Saturday, February 23, the Inn Circle All-Stars will present a conce tribute to Sarah Vaughan. Both progra are free, but tickets to each must picked up at the first-floor informati desk starting at 12:15 the day of the pe formance. For more information c (212) 873-1300, ext. 514.

The Black West

One-fourth of all cowpunchers w

e blue of the sea, the bright sky, the far as and sunlit shores" of the Pacific re-n. Working with Eugene B. Bergmann, igner in the Museum's Department of nibition and Graphics, she approved basic plans for a hall that achieves this ct.

The hall is designed so that color-coded pet islands appear to float on a sea of e terrazzo tile. Each zone focuses on of six major cultural areas of the Pa-c—Australia, Indonesia, the Philip-es, Melanesia, Micronesia, and Polyne-—and is set off by the colors of the peting and display cases.

The life styles of four regions are de-ted by models, each approximately ee feet by six feet, and built on a scale three-eighths of an inch to one foot. ey illustrate in detail a Samoan village, temple dancers of Bali, the aboriginal ial rites of the snake clan in the rramunga group of Central Australia, and a Manus (Admiralty Islands) village.

The Manus model is the only remaining three-dimensional document of the life style of a Manus water-village. Constructed in 1932, a few years after Mead completed her first collection in the Admiralty Islands, the model depicts a village built on stilts in a lagoon. A typical Manus village consisted of seventy-five huts, and inhabitants used dugout canoes to travel from home to home. The people of this region abandoned this life style after they fell under the influence of other cultures, and their descendants now live on land.

While planning the new hall, Mead wrote: "Not only will our children see these things. The descendants of Hawaiians, Trobrianders, Balinese, and Australians will come to America as students, and here in the Museum they will find the stone tools and weapons, the fragile ornaments and precious objects made by their ancestors cared for and safe."

rove cattle up the Chisholm Trail were ack, thousands of blacks joined Indian ibes, and 20 percent of the U.S. Cavalry ere black. *The Black West: Black Cow-oys and Indians*, a lecture and dramatic terpretation to be presented on Wednes-ay, February 13, at 7:00 P.M. in the Audi-rium, will reveal many other little-nown facts about the West. This free rogram is made possible in part by a gift om the Evelyn Sharp Foundation.

lonkey of the Clouds

The Peruvian yellow-tailed woolly mon-ey, one of the rarest monkeys in the orld, lives in a small area of the Peruvian ndes. It had been presumed extinct for early fifty years until one was spotted in 974. On Sunday, February 14, at 11:00 M., 1:30 and 3:30 P.M., a film and slide rogram about this elusive monkey will be resented in the Kaufmann Theater. lembers will also learn about world-wide nservation efforts to save endangered rimates. Presented with scientists from e World Wildlife Fund, the program is ee and open only to members. For ticket formation call the Membership Office (212) 873-1327.

arwin's Ark

Philip Appleman will read selections from his new book of poetry, *Darwin's Ark*, inspired by Charles Darwin's *Origin of Species*, in the Hall of Ocean Life on Tuesday, February 5, at 7:30 P.M. The free program is open only to members; contact the Membership Office at (212) 873-1327 for ticket information.

1985 Spring Lecture Series

The Museum's adult lecture series will begin in February. This year's special lectures include Variety of Jewry: An Ethnography; Alaska: Giant of the North; Wildflowers; Islamic Arts and Sciences; World Music Festival; Landscape for Travelers; Origami; Foraging for Dinner; Animal Drawing; Insects; Anthropology Through Film; Travel Photography; and Saturday Field Walks in Botany. For information about lecture schedules and prices, please contact the Education Department at 873-1300.

Planetarium Events

The Violent Universe is the Sky Show at the Hayden Planetarium. Narrated by Vincent Price, this show delves into the forces that shape our universe. Topics covered include black holes, exploding galaxies, and the big-bang theory. For information about this and other Planetarium programs call (212) 873-8828.

50% OFF NORMAL RETAIL

100% Merino Wool Mattress Pad

MANUFACTURER DIRECT

A tradition in Europe is sweeping America. Soft 100% Merino Wool cushions and cradles your body for a deeper, more restful night's sleep. Even the best mattress creates pressure points on the shoulders, hips and back. Soft, thick Merino Wool conforms to the contours of your body, relieving pressure points. Many people report they fall asleep faster, enjoy a more restful sleep and wake up feeling completely refreshed.

Wool is a natural insulator. In winter the pad retains body heat to keep you warm. In the summer, the pad keeps you cool by absorbing moisture.

The Wool Bureau has given this product the Superwash® designation. It can be machine washed and retain its original softness, resiliency and durability.

We use Merino Wool, absolutely the finest wool money can buy. Finally, we manufacture the pad ourselves and sell it directly to you, eliminating the middleman and retail markup and eliminating half the cost.

If you don't enjoy the best night's sleep you've ever had, simply return it to us for a complete refund. Delivery: Immediate.

Hill Tribes of Thailand

by Alain Y. Dessaint

PEOPLES OF THE GOLDEN TRIANGLE: SIX TRIBES IN THAILAND, by Paul and Elaine Lewis. *Thames and Hudson, $29.95; 300 pp., illus.* HIGHLANDERS OF THAILAND, edited by John McKinnon and Wanat Bhruksasri. *Oxford University Press, $49.50; 358 pp., illus.*

The dozens of ethnic groups that inhabit the fragmented highlands of Thailand and neighboring Burma, Laos, and China have been much in the news over the past decade. International issues, from political insurgency to opium growing, brought them to public attention; war forced some to resettle in the United States and elsewhere. Most of these cultures, visibly distinguished from each other by colorful tribal costumes, are agricultural, and some are still nomadic, depending upon slash-and-burn cultivation.

But the last ten years have seen imme changes. New roads that crisscross no ern Thailand have ended the physical a psychological isolation of all but the m remote villages. Where once it took ho or even days of walking to arrive at a lage from the nearest road, one can n ride four-wheel-drive pickup trucks within a few minutes of most highland lages, at least in the dry season. But ru roads have brought mixed blessings. the one hand, there is easier access to m ical facilities, markets, and schools; on other, there is entanglement in a consu society, loss of faith in traditional cur methods, and children brought up lea ing a new language and a new culture. creasing numbers of hill tribesmen n have radios (there are now daily bro casts in each of the major highland l guages), tape recorders, and even Ja

Lahu She Leh village

Hansjörg Mayer, *Peoples of the Golden Tri*

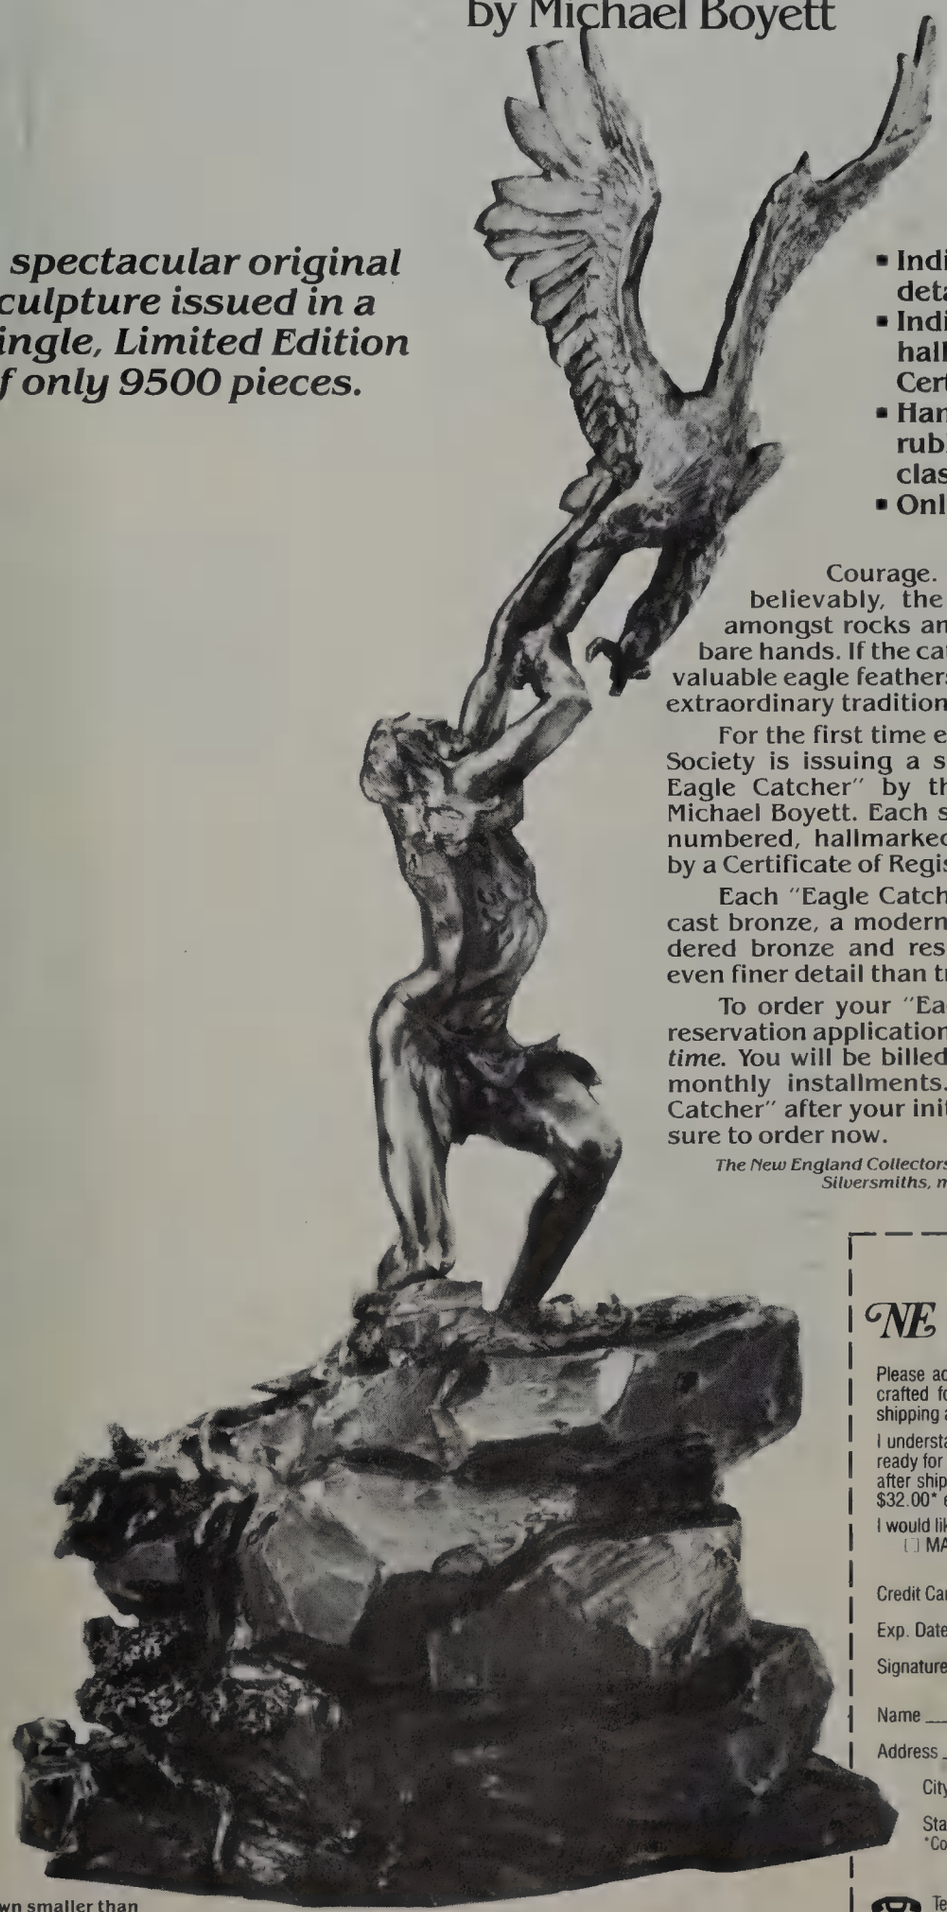
Presenting

"The Eagle Catcher"

by Michael Boyett



Shown smaller than actual size of 9 7/8" high.

A spectacular original sculpture issued in a single, Limited Edition of only 9500 pieces.

- **Individually cast in brilliantly detailed cold-cast bronze.**
- **Individually serially numbered, hall-marked and registered. Certificate of Registration.**
- **Hand-finished and hand-rubbed to the rich patina of classic bronze.**
- **Only $125.00**

Courage. Bravery. Incredible daring. Unbelievably, the Shoshone eagle catcher hid amongst rocks and captured live eagles with his bare hands. If the catcher survived he was wealthy in valuable eagle feathers, rich in tribal honors. It was an extraordinary tradition.

For the first time ever, the New England Collectors Society is issuing a strictly Limited Edition of "The Eagle Catcher" by the acclaimed American artist Michael Boyett. Each sculpture is individually serially numbered, hallmarked, registered and accompanied by a Certificate of Registration.

Each "Eagle Catcher" is individually cast of cold-cast bronze, a modern sculptor's blend of finely powdered bronze and resins. Cold-cast bronze captures even finer detail than traditional hot-casting.

To order your "Eagle Catcher" simply return the reservation application. *You need send no money at this time.* You will be billed later for the first of four equal monthly installments. You will receive your "Eagle Catcher" after your initial payment has been made. Be sure to order now.

The New England Collectors Society is a subsidiary of Reed & Barton Silversmiths, master craftsmen since 1824.

"The Eagle Catcher" Y6

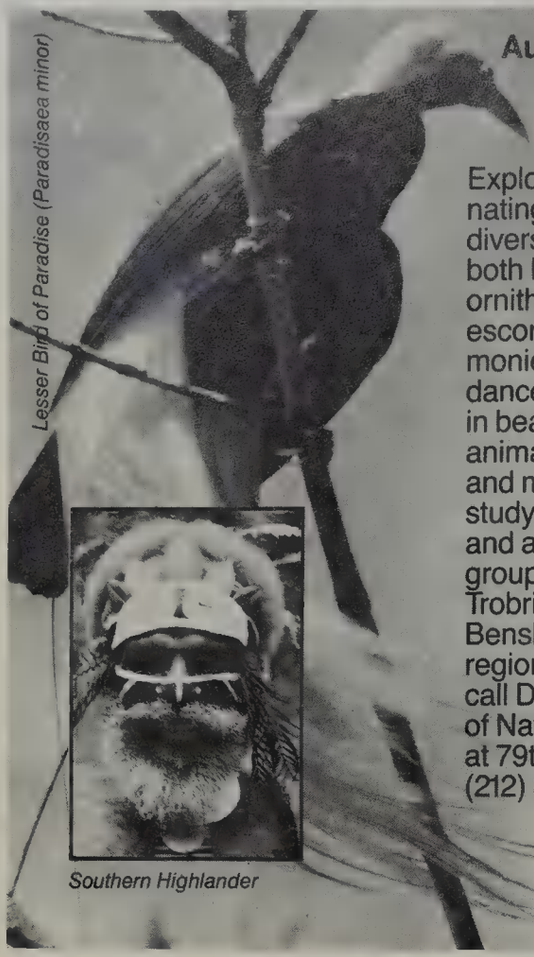
DISCOVER PAPUA NEW GUINEA

With the American Museum of Natural History



Lesser Bird of Paradise (Paradisaea minor)

Southern Highlander

August 27 to September 22, 1985

Explore one of the world's most fascinating islands with an extraordinarily diverse natural and cultural history. Join both Mary LeCroy, American Museum ornithologist, and an anthropologist/escort as we witness Stone Age ceremonies incorporating spectacular dances and music; swim and snorkel in beautiful coral atolls; view unusual animals including birds of paradise and marsupials; visit tribal markets and study the island's unique architecture and art forms. With expert guidance our group of 18 participants will discover the Trobriand Islands, the Highlands, the Bensbach, Sepik and Karawari River regions. For further information write or call Discovery Tours, American Museum of Natural History, Central Park West at 79th Street, New York, NY 10024, (212) 873-1440.

Today, Thai songs and rock music vie wi
the roar of motor vehicles to break the t
ditional serenity of the mountain villag

A spate of books have been recen
published about the highland people
northern Thailand, but the two books u
der review, one academic and the oth
aimed at a general audience, are the be
of the lot.

Peoples of the Golden Triangle conce
trates on the traditional cultures of t
Hmong (Meo), Mien (Yao), Karen, a
three Yi groups: the Akha (about who
Paul Lewis has also published a four-v
ume monograph), Lahu, and Lisu. This
the most attractive and best written of t
recent books. It manages to combine t
usefulness of a culture summary with t
liveliness of personal vignettes and pa
after page of exquisite color photograph

Paul and Elaine Lewis, both mission
ies with an anthropological bent, ha
spent more than three decades living wi
and studying the hill tribes of Thaila
and Burma. They have organized th
book in terms of such cultural themes
harmony, independence, continuity, a
family primacy: the Karen desire for ha
mony with their environment, the supe
natural, their neighbors, and one anoth
the Hmong desire for economic, soci
and religious independence; the Mien d
sire for propriety; the Lahu desire f
blessings such as health, wealth, and fre
dom from worry; the Akha desire for co
tinuity with their ancestors and histor
and the Lisu desire for primacy of th
family, clan, or village. One could quibb
that all six goals are held by each of t
groups discussed, but as long as the read
recognizes the obvious oversimplificatio
this approach does much to integrate t

P·O·T·T·E·R·Y

AMERICAN • INDIAN • POTTERY

LAGUNA

HOPI

A 15" × 22" wood display unit is provided at no additional charge to house your collection. The pieces range in height from 2¼" to 4¼".

NAMBE-POJOAQUE

For centuries Indian pottery has been both a functional tool and a source of artistic pride. From the clay beneath their feet, generations of craftsmen have fashioned vessels of utility, beauty and value.

As American Indian Pottery has now become one of the most prized possessions of collectors world wide, we are proud to introduce and make available this carefully reproduced collection of twelve pots. Each piece exemplifies a classic form and design from one of America's most noted pottery making tribes.

To amass this collection would take extensive study, travel and expenditure. But now, by subscribing to American Indian Pottery, you may acquire this entire collection of twelve pots at the convenient rate of one piece per month and at the very attractive price of just $17.50 for each vessel. To insure your enjoyment and understanding of American Indian Pottery, educational information will be provided at no additional charge. A certificate of authenticity will complement each piece.

The San Ildefonso bowl reflects the significance of eagle feathers, the rich earthen colors of the Santa Clara pot seem to speak of red canyon walls often seen in the southwest, while the Jemez bowl tells of a deep religious association with their ceremonial worship chambers or kivas. Each representative vessel is distinct in shape, color and design. Together they tell a story of the beauty created from the basic elements of earth, fire and water.

In any room, with any decor, these earthenware vessels will be an inspiring focal point. Reflecting upon the history and artistry of this collection will instill a sense of understanding and enjoyment for years to come. A handsome wood shelf unit is provided with the collection at no additional charge.

This magnificent series of traditional American Indian Pottery is now available.

To insure that you will not miss this opportunity, reserve your set by calling our toll free number, 1-800-328-6488 (US), 1-800-845-8834 (Arizona only), or call collect 1-602-526-0949. You may also mail the coupon provided below and begin building your collection. Your satisfaction is of course completely guaranteed.

Please enter my subscription for the **"American Indian Pottery"** series. Each earthenware piece will be sent to me at the rate of approximately one per month and I will be billed $17.50 each plus $1.50 for shipping in advance of shipment (Arizona residents add applicable sales tax).

book while differentiating among six si
lar yet distinct ethnic groups.

But the really striking characteristic
this book are its photographs and des
(for which Hansjörg Mayer deserves
ognition). Even those with no interest
the subject matter will admire the arti
quality of the photographs of village
and material culture: embroidery, sil
jewelry, ivory ear ornaments, wood, h
and-silver opium pipes, musical inst
ments, basketry, batik, agricultural im
ments, houses, hunting weapons,
traps. This is the next best thing to visit
a museum!

In fact, the enchantment of the c
and warmth of these photos is at odds w
the real world of northern Thailand.
the authors remark, "The picture
peaceful tribal people living in the prist
beauty of cool, quiet hills" must be
anced by the reality of "staving off h
ger, caring for sick children, being vict
ized because of one's illiteracy, be
denied citizenship, or being gawked at
tourists and laughed at by townspeopl

The romantic may lament the pass
of traditional cultures, but who can d
that some individual highlanders are
ter off because they went to sch
learned to read and write, even earne
college degree, or are able to buy and
in a free market? Increasing numbers

Silver bracelets worn primarily by Lah and Akha men

ghlanders are attending Thai schools
d universities, and many surprise me by
e sincerity with which they want to use
eir learning for the benefit of their peo-
e, not just for themselves. Some hill
besmen work as guides for tour oper-
ors in the city of Chiang Mai, learning
nglish in the process since most of their
ents are American or European. Others
ve found employment with the Border
trol Police. Some 50,000 highlanders,
ostly Meo and Yao, have been resettled
the United States, Europe, Canada,
ustralia, and South America. Many
ore have spent time in these countries
udying, working, or simply visiting.

Highlanders of Thailand devotes more
ace to these matters but is primarily for
e specialist. The contributors have all
en associated with the Tribal Research
entre in Chiang Mai, which, as W.R.
eddes discusses in his introduction, has
elf been accused of being an outside in-
gator of change. Some of the essays are
oad introductions to the various high-
nd groups (including not only the six
entioned above but also the northern
nai, highland Chinese, and several small-
groups); but most chapters address nar-
wer concerns, such as shamanism, sex
les, and the traditional treatment of
ath. This is the best of the academic
oks on the subject, for both its breadth

Lisu children

and for the quality of its analyses. There are nevertheless some pitfalls to keep the student awake: a clarifying footnote should certainly have been added to the statement that "most Pwo Karen, Lahu Nyi, Lisu, and Northern Thai avow Buddhism." An accompanying table that indicates 61.1 percent of Pwo Karen, 71 percent of Lahu Nyi, and 81.8 percent of Lisu in a survey group were Buddhists proves only that the group was unrepresentative or adept at answering questionnaire incorrectly. The majority of the first three hill tribes are still animists.

An interesting chapter by Erik Cohen discusses tourism in the highlands, a phenomenon that began about fifteen years ago and has accelerated since. Whereas ten years ago few highlanders ventured into Chiang Mai, northern Thailand's only city, Hmong and a few other tribals are now regular vendors at the colorful night bazaar that spills over into the downtown streets. Thai, Chinese, Burmese, Indian, Europeans, Australians, and Americans jostle each other. In spite of the language problems, the tribal merchants are equally astute with a French tourist or a Bangkok Thai. They sell not only items from their own villages but also those of other hill tribes and even resell Thai, Burmese, and Nepalese trinkets. In addition some three dozen small tour operators offer treks to hill tribe villages. The customers are mostly young Americans or Europeans with little knowledge of the customs or languages of the people they visit. Some frequently visited villages have come to rely on the sale of souvenirs (they are no longer handicrafts, and some items, such

John Hobday, *Peoples of the Golden Triangle*

tablecloths and placemats, have no ıce in traditional culture). Homemade othing and homespun cloth is rapidly ing way to Japanese synthetics and othing made on sewing machines. There e changes in highlander behavior, ought, and values as well. The danger is at these villages are fast becoming hun zoos: their inhabitants are inured to e outsiders who come to stare and photoaph them for a few minutes or hours, en leave.

A sign I recently saw in Chiang Mai ems to sum up the changes that have en wrought these past ten years: Newly discovered hill tribe village! Only ır groups have visited before! Three-day k leaves Thursday, 600 baht!" (about 0). Even the tour operators recognize at once a village has been visited by too any tourists, it is spoiled and no longer orth as much. Yet the tour operators emselves are participating in the deuction of traditional cultures. And by blicizing "little known" cultures to the tside world, do the recent books about e hill tribes of Thailand also contribute their destruction? Will the information ntained in these books lead to more ranal policies or behavior on the part of tsiders or will it merely pique our curiosand further encourage more gawking arists?

ain Y. Dessaint is Asian specialist with e Business Council for International derstanding in Washington, D.C. His norities of Southwest China was published in 1980 by Human Relations Area les, New Haven, Connecticut.

Own America's First Silver Dollar

Original 200 year old coins that were legal tender of our 13 colonies

Minted from 1772-1821, these silver dollars were the most popular coins of our 13 colonies.

January, 1985. MONTPELIER, VERMONT — International Coins & Currency, Inc. a national distributor of numismatic coins, is offering for sale a limited number of original 200 year old coins — among the first large silver dollars minted in the Americas. These magnificent silver coins once circulated in our original 13 colonies and the early USA. Because of their high silver content and popularity, Thomas Jefferson recommended that they become official legal tender of the United States of America.

Minted from 1772-1821, these silver dollars were the most popular coins of our 13 colonies and were used as legal tender in the USA up until 1857. As collectors and investors turn to American coin classics, these scarce silver dollars are becoming increasingly sought-after and desirable.

Struck at the Americas' oldest mint in Mexico City and denominated 8 Reales, these silver dollars were the forerunners of the first U.S. silver dollar minted in 1794 — and served as the most favored trade coin in the world. Yet huge silver melts and the fact that relatively few were saved from destruction make these coins "sleeping" classics. Each silver dollar is a big 39.5 mm in diameter, contains 27.07 grams of .903 pure silver, and each comes with a Certificate of Authenticity attesting to its fine quality and genuine status. This guarantee never runs out. Because the supply was originally discovered in the Far East, genuine "Chinese merchant markings" are often visible and serve to authenticate the coins.

Because of the age and historical significance of these coins, you might expect to pay up to several hundred dollars for one. But while supplies last, they are available on a first-come, first-served basis for $75 each — and you can save up to $75 by buying more than one. International Coins & Currency, Inc. is offering for sale a limited number of these coins to collectors and investors at:

1 coin $75; 2 coins $150;
3 coins $215 (save $10);
5 coins $345 (save $30);
and 10 coins $675 (save $75).

There is a strict limit of 10 coins per customer. Your 100% satisfaction is guaranteed — you may return your order for a prompt no-questions-asked refund within 15 days (less postage and insurance of course).

To order your coins by credit card, call toll free at 1-800-451-4463, 24 hours a day, 7 days a week (including Sundays).

If you prefer, send check or money order in full amount to: International Coins & Currency, Inc. Dept. 696, 11 East State, P.O. Box 218, Montpelier, Vermont 05602. Add $3.75 for 1 coin or $5.00 for more than 1 coin to cover postage and insurance. Special presentation cases for individual coins are also available at $2.50 each. Mr. Douglas Schneible, ICC's Numismatic Director is Life Member No. 1305 in the American Numismatic Association. All coins are available for prompt delivery.

LaRue-Pine Hills, Illinois

by Robert H. Mohlenbrock

Not long ago I guided a group of naturalists from Chicago through an area in southwestern Illinois just forty miles from where I teach. As we stood before a spring-fed swamp that stretched to the base of 350-foot bluffs, one member of the group exclaimed appreciatively, "It sure doesn't look like Illinois!" No, LaRue-Pine Hills, a five-mile by two-mile strip running north–south in the Shawnee National Forest, does not evoke the flat fields of corn and soybean that dominate the central and northern portions of the state. Instead, one finds limestone cliffs like those in the Missouri Ozarks, swampland that mimics parts of Louisiana, and densely wooded ravines reminiscent of the Appalachians. The plant and animal life also reflects a relationship to these peripheral areas.

Several events shaped the character of the region and made it a biological crossroads. The uplifting of the Ozark Mountains, the inward spread of shallow Paleozoic seas, the crushing and crunching of continental glaciation, the strong westerly winds blowing across the prairies and plains, and the development of the Appalachian Range have all left their mark. As a result, LaRue-Pine Hills is the most diverse natural area of its size in the Midwest and possibly in the entire nation. Biologists who have used it as an outdoor laboratory for more than a century have found that it supports a wide selection of Illinois's plant and animal species, including some that are otherwise rare in the state. Unfortunately, certain of them have been nearly extirpated by overzealous collectors. Prodded by local naturalists, the U.S. Forest Service now manages LaRue-Pine Hills as an inviolate ecological zone, where plants, animals, and all things natural are not to be disturbed.

The Pine Hills part of the name refers to a pine-laden ridge of chert-bearing limestone that extends along the eastern edge of the area. The sheer, west-facing limestone cliffs, with steep, gravelly talus slopes, result from the same uplifting that, some 400 million years ago, created the Ozark Mountains to the west. As in adjacent southern Missouri, some of the limestone has dissolved, exposing acidic, orange-red pebbles of chert. Plants adapted to this habitat in Missouri have also found a home in this corner of Illinois. One is the shortleaf pine, whose presence was cause for comment as early as 1860, when Dr. Frederick Brendel, an immigrant German physician who lived in Peoria, wrote of it in *Prairie Farmer* magazine. Aside from a few ridges in the Pine Hills, this tree inhabits only one other Illinois location, although it is abundant in the Missouri Ozarks. Growing in the chert beneath the pines are pink azaleas, also confined in Illinois to this extension of the Ozarks. Other species range from colorful wildflowers, such as Boott's goldenrod and bird's-foot violet, to inconspicuous grasses and sedges.

The dry, rocky ridges also support numerous post oaks, blackjack oaks, black hickories, and red cedars, which grow stunted and gnarled in response to the harsh environment. Hikers clambering over the ridges are often surprised to emerge abruptly from the woods into grassy, treeless areas. Because these isolated openings harbor some of the same kinds of plants common to the great prairies to the west, they are called hill prairies. In the Pine Hills, they range in size from less than an acre to about two acres, although farther north on the bluffs along the Mississippi River, hill prairies may extend over several hundred acres. They develop mostly on west-facing slopes, where the hot afternoon sun beats down relentlessly on summer days, causing such dryness that trees cannot grow. Westerly

Robert H. Mohlenb

The yellow-flowered bladderwort of LaRue Swamp.

winds, which contribute to drying the slopes, pick up seeds from the prairies and plains and propel them eastward to lodge in these openings. They sprout into grasses, such as big and little bluestems, Indian grass, and the curious-looking side oats grama, and into showy wildflowers, such as pink prairie phlox, yellow prairie evening primrose, butterfly weed, prairie clovers, and rosinweeds.

The rare eastern wood rat builds its nests of twigs and leaves along the narrow ledges of the limestone cliffs. This is a true pack rat, usually incorporating anything it can find into its nest. At some time long past, it probably migrated into the Pine Hills from the Missouri Ozarks. Another phenomenon of the erosion-pocked cliff faces is one 200-foot stretch that is a haven for small evergreen ferns known as spleenworts. No fewer than nine different kinds grow here, more than at any other place in the world. Why there are so many, biologists aren't sure, but in the crevices of chert and limestone, side-by-side combinations of acidic and basic soils vary to an extent rarely repeated in nature.

At the foot of the limestone cliffs and talus slopes lies a vast area of standing water known as LaRue Swamp. Named after a now-abandoned whistle stop along the nearby Missouri Pacific railroad, the swamp is partly fed by clear springs that issue from the base of the cliffs. These water sources harbor the Ozark spring cave fish, a small, blind organism whose eyesight became dispensable as it evolved in the darkness of springheads. As its name implies, this fish is associated with similar springs in the Missouri Ozarks.

After the uplifting of the Ozarks, Pale zoic seas covered the low-lying areas southern Illinois. When these shallow w ters subsided, the extensive swampla left behind became inviting habitat f scores of coastal plain species. Organisr migrated up the Mississippi Embayme the tongue-shaped trough that exten from near the mouth of the Mississip River north into southern Illinois. A though the swamps now remaining are b vestiges of a former era, migratory bir that land in the wetlands probably co tinue to carry plant species along this co ridor. Among the species that establish themselves in LaRue Swamp were t rusty-flowered swamp iris and the spon plant, a floating, flowering plant whc leaf cells inflate with gas bubbles to ke the heart-shaped leaves buoyed up to t water's surface. Other southern plant sp cies include the tupelo gum and pumpk ash, two trees whose swollen trunk bas help anchor them in their watery hon The southern rice rat also made its w northward into the swamp, as did lar numbers of fish, reptiles, and amphibia including the banded pygmy sunfish a the green water snake.

Floating on the surface of LaR Swamp, often in sufficient numbers to c scure the water completely, are duc weeds, the smallest flowering plants in t world. Each one consists of a tiny gre body, which may or may not have roo The tiniest of all is *Wolffia*, with a bo less than one millimeter in diameter. C rare occasions, duckweeds produce flo ers so minute that they can only be se through a microscope. Botanists recogni

ɔut thirty different kinds of duckweeds
he world, including seventeen in North
nerica; of these, eleven appear in
Rue Swamp. Occasionally interrupting
continuity of the duckweeds are
tches of wine-colored, floating mosquito
n and yellow-flowered bladderwort.
e latter's underwater structures bear
y traplike bladders that suck in minute
uatic animals for nutrition.

On slightly elevated areas adjacent to
swamp, in the coves of the limestone
ffs, the rich, moist land supports stately
ests of tulip poplar, American beech,
cumber magnolia, and Ohio buckeye,
es with an Appalachian connection.
veral hundred miles to the east, the
ɔpalachian Range is four to five thou-
nd feet above sea level. The drainage
tterns that have developed from the
ɔpalachians have opened up paths of mi-
ation through which these elements
ay have come. The cool, moist coves are
o perfect for spring wildflowers that are
ted to the shade. Freed from compe-
ion, they grow so thickly that walking
thout trampling them is difficult. There
ɔne acre of uninterrupted bluebells; an-
ner cove is filled with Gleason's white
llium and yellow celandine poppy; else-
ere, Miami mist forms a light blue haze
ross the forest floor.

Four great glaciers have ground their
y south into Illinois, pushing before
em anything that stood in the way. The
epest penetration, made by the Illi-
isan glacier some 200,000 years ago,
ɔpped a few miles north of LaRue-Pine
lls, but the groundwork was established
new routes of migration for plants and
imals. The bulblet hemlock, a yellow
ɔsestrife known as swamp candles, and
ch fish as the spottail shiner and the
rthern hog sucker may have reached
Rue-Pine Hills along this pathway.

The area's diversity seems inexhaust-
e. Kenneth Weik, a botanist at Lake
rest College, studied LaRue Swamp for
achelomonas, a genus of microscopic,
glenalike algae. His identification of
irty-three different species of these
een spheres—including two new to sci-
ce—tripled the number previously
own in the state. Not to be outdone, Jay
cPherson of nearby Southern Illinois
niversity has recorded fifty kinds of
nkbugs from the Pine Hills; possibly the
gion now deserves the unenviable title of
Stinkbug Capital of the World."

*This Land" highlights the biological
enomena that can be explored in the 153
S. national forests. Robert H. Mohlen-
ock is a professor of botany at Southern
linois University at Carbondale.*

The Safari Jacket

Whether you're out in the bush or out on the town, you will find this a versatile and practical garment.

Ruggedly constructed of tightly woven twill cloth in an easy-care and breathable blend of 65% cotton/35% polyester.

The four button-through flap pockets are roomy and secure enough for all your essentials, the X-stitched epaulets perfect for securing camera straps and other equipment. Adjustable side tabs for full or more contoured fit. No belt to flop around or get lost. Tailored with single-needle reinforced sleeving and two deep action-back pleats for ease of movement. Roomy enough to be worn over a shirt or sweater.

Manufactured for us by Van Heusen...backed by the Baker Street Shirtmakers guarantee of satisfaction or your money back.

The Safari Jacket...for wherever your sporting life takes you. Only $34.50 Long Sleeves, $29.50 Short Sleeves. In Khaki and Olive Drab, of course.

FAMOUS FEDORA

19.95

A revival of an old favorite. You saw a fedora like this in "Indiana Jones & the Temple of Doom" — reminding us all of how much adventure a man in a fedora can find. Our version is of special wool felt, finer textured and stiffer for improved shape retention over ordinary felts. Features a tapered 5" crown with triangular crease and 2 side tucks, 2½" brim and a deep brown grosgrain band. Fully lined with rayon satin. Sizes 6¾ thru 7½ (runs large). Money-back guarantee.

Introductory Special!

VINTAGE ADVENTURER JACKET
Regularly $198
Now Only $168
Save $30!

This terrific leather flight jacket is a famous favorite! You saw one like it in "Indiana Jones & The Temple of Doom" in 1984. Clark Gable wore one flying an air race equipped P-35 in the 1939 movie, "Test Pilot." But you don't have to be a movie star or a pilot to appreciate the comfort and superb quality here. Features double entry pockets with zippered top, hidden inside stash pocket, zip front with wind flap, full lining, bi-swing back and underarm gussets for free movement. Plus it offers the special vintage effect of worn, aged leather in a completely new high-quality garment. Sizes 36 thru 50. Money-back guarantee.

The Case of Johanna's Quail

Can a new recipe be a success not only on the dinner table but also in a court of law?

by Raymond Sokolov

In the supermarket yesterday, we bought a package of four frozen quails. The plump little birds cost less than $3, which made us feel good about the world. And we felt even better when we ate them at Sunday lunch, after having spent an absolute minimum of time with culinary fussing.

The basic recipe came right off the package the birds were sold in. It advised moistening the quails in "Italian salad dressing," then broiling them over an outdoor fire for twenty-five minutes, and basting them with more dressing every five minutes.

Much was left out in this recipe. It gave the consumer no sense, for instance, of how close to the outdoor fire the birds should be. More important, it made no specific recommendation about the contents of the "Italian" dressing. Still and all, it was hard to go wrong, and the tackiness of the recipe concealed its basic similarity to a great many, much more sophisticated recipes that essentially consist of meat marinated in a flavored vinaigrette dressing and then broiled or roasted.

This procedure is at the heart of almost all barbecuing and of much classic game cookery. Therefore, sensing where we were on the culinary map, we went ahead with the manufacturer's recipe, modifying it in a way that was uniquely ours but heavily dependent on tradition. We mixed up our own vinaigrette, soaked the birds in it, and then set them to broiling in the oven. At a certain point about halfway along, my wife was inspired to smear the quails with red currant jelly, which is a traditional component of game sauces. The jelly was at room temperature—therefore solid and hard to spread. It fell off the quails into the pan, where it melted into the juices that had collected there. Seeing that she had inadvertently created a fine basting liquid, but having no baster at hand, she took tongs and stirred the little birds through the liquid in the pan, efficiently coating them with it.

The finished quails were delicious. And I think Mrs. Sokolov is entitled to claim this method as her own and to publish the recipe as "Quail Johanna" or even "Cailles Rôties à l'Instar de Jeanne." And until recently I would have thought that nothing in the law then prevented a reader from republishing the same recipe as his own, for example as "Roast Quail Casimir O'Brien." Certainly, nothing I knew of, beyond common decency or the risk of being stigmatized by other food writers, would have compelled Mr. O'Brien to seek permission from Johanna for the use of her work.

All that may have changed last su
mer, when the American expatriate co
ing teacher Richard Olney took legal
tion against the book *Richard Nelso
American Cooking* and its publish
New American Library (NAL). Oln
claimed the new book contained thir
odd recipes plagiarized from his much
mired *Simple French Food* (Atheneu
1974).

In a consent judgment, NAL agreed
stop publishing and selling the Nels
book, and Olney was paid an undisclos
sum reported to be in the low five figur

A consent judgment does not have
effect of legal precedent, but the Nels
case could have what lawyers call a ch
ing effect on people who used to feel
compunction about borrowing the recip
of others and reprinting them without p
mission or attribution.

In the bad old days before the Nels
case, publishing lawyers would advise y
that no one could assert a right of prope
in an individual recipe. Originality
method was almost impossible to pro
while originality of expression was an e
nescent concept, easy to muddle with
change of a line or a phrase that would
able a pirate to claim the slightly edit
new text as his own.

Apparently, if the Nelson case is a s
of the way judicial winds are blowi
Johanna's quail recipe (which I have pu
lished here with her permission and for
consideration of one new Bolivian alpa
sweater, brown, purchased at the gift sh
of the Organization of American States
Washington, D.C., for an undisclos
price in the high two figures) is now
fendable as private property.

While I am glad and proud about t
particular turn of events, I question

Vivaldi's "Unbridled Fantasy" At An Extraordinary Price!

The 3 records of L'ESTRO ARMONICO, list price—$24.00—can be yours for ONLY $2.00 when you join the *Musical Heritage Society.*

Dear Friend of Great Music,

Vivaldi is one of the most popular baroque composers, and the 12 concerti of *L'estro armonico* ("Unbridled Fantasy in the Realm of Music") are perhaps his finest accomplishment. These works burst upon the musical scene in 1712 to stun and dazzle the music-loving public. *L'estro armonico* is one of those musical milestones that broke down the old barriers and opened up entirely undreamed of areas of beauty and creativity. Never before had any composer achieved such total mastery of the sound palette while creating such stunning works of symphonic richness and abundance; no previous works provide such an atmosphere of freshness, lightness, and sheer virtuosity.

Now you can own this 3-record or cassette set of the complete *L'estro armonico* (a $24.00 value) for only $2.00 upon acceptance of your application for membership in the Musical Heritage Society.

THIS SUPERB COLLECTION IS YOURS FOR ONLY $2.00!
AVAILABLE IN RECORDS OR CASSETTES.
Send for it TODAY!

GET "SELECTIONS FROM OUR MASTER CATALOG" FREE!

With your introductory recording, the Society will include its "Selections from Our Master Catalog" containing records and cassettes covering every musical period, carefully chosen from our collection of almost 3,000 records and cassettes.

The Musical Heritage Society issues each year about 200 new recordings of the music of such great masters as Albinoni, the Bachs, Beethoven, Berlioz, Buxtehude, Charpentier, Corelli, Couperin, Gluck, Handel, Haydn, Lully, Monteverdi, Mozart, Pergolesi, Purcell, Scarlatti, Schubert, Telemann, Torelli, Vivaldi, and many others. Its recordings cover all musical periods: Medieval, Renaissance, Baroque, Rococo, Classical, Romantic, and Modern. Over 200 of its recordings have been honored with the coveted GRAND PRIX DU DISQUE and other international awards.

MUSIC THAT CAPTIVATES!

Even though the Society's records are of serious music, it has some that are "hits!"

Take MHS 1100 (Vivaldi's Concerto for Mandolin) in our catalog, for instance. When it was played over a pops radio station frequently for a short period of time, over 80,000 records were sold as a result!

Or consider the Society's MHS 1060 (Pachelbel's Canon). This record, when played by radio stations, results in an avalanche of calls that tie up their switchboard for hours afterwards!
We are certain that among the Society's 3,000 records and cassettes there must be many that will captivate you.

HOW THE SOCIETY OPERATES

The Society's recordings are not sold in stores. They are offered directly through the MUSICAL HERITAGE REVIEW magazine at three-week intervals. As a member, you'll enjoy substantial savings. Member prices are $5.45 per LP or cassette (Canadian members prices are $7.50) plus postage and handling. (Deluxe-boxed editions, digital recordings, and compact discs are slightly higher).

When the Society receives your request, it sets up an account in your name and begins sending your free one-year subscription of the MUSICAL HERITAGE REVIEW for your edification and delight. There is NO PURCHASE OBLIGATION and you may discontinue the complimentary subscription at any time. As a subscriber, outstanding selections will be scheduled for shipment to you from each issue—but there is no obligation to accept them...order only those you want when you want them!

A special response form will be enclosed with each Review...and you may use it to order or reject any selections simply by mailing it by the date specified. And if you want only the Featured Selections, you need do nothing—they will be shipped to you automatically. What's more, you'll have at least 10 days in which to make your decision—if you ever have less time than that, just return the Featured Selections at our expense, for full credit.

ONE OF THE TRULY GREAT RECORDINGS OF THIS DECADE! "A REVELATION IN MUSIC!"

To receive this splendid recording simply mail the request form provided below along with $2.00. We're confident that you'll so treasure this masterpiece that you'll be moved to acquire more of the Society's fine recordings.

OFFER OPEN TO NEW MEMBERS IN THE CONNECTING UNITED STATES AND CANADA ONLY.
CANADIAN MEMBERS WILL BE SERVICED FROM CANADA.

logic apparently underlying the Nelson-Olney agreement, which is, at any rate, difficult to specify, since the court did not enunciate a doctrine.

Did the case hinge on the weak argument that the formula expressed in Olney's recipes was uniquely his? Cooking is not, after all, a field like chemical engineering, in which new discoveries are made daily and promptly reported in journals where they can be easily retrieved and identified. Indeed, almost no cookbook writer alive today does more than recombine processes invented long ago and reinvented by many hands thereafter. Perhaps, every once in a great while, someone will hit upon a new way of, say, poaching eggs, but this is a rare occurrence at best.

More often, improvisation in the kitchen will produce a dish a good cook thinks is original in the way that it recombines standard ideas. I think Johanna's quail is such a recipe. I also think it would be impossible to prove that claim in court. How can we be sure that no one in all of recorded and unrecorded time didn't slip currant jelly into pan drippings, then douse a quail with the resultant juice?

The Nelson-Olney agreement, if it is based on anything of substantial plausibility, was most probably based on uniqueness of language. In other words, if Mr. O'Brien should happen to reprint the verbatim text of the recipe below, without permission or attribution, he would have exceeded the bounds of fair use, and Johanna Sokolov could sue him with a fair presumption of making him wince in his pocketbook.

Naturally, I am inclined to see justice in this, as it affects my helpmeet (and my own rights over my own text). But in that parenthesis lies the heart of the matter. I wrote the text, which is, I think, the only aspect of the recipe that anyone can securely own. Doesn't this state of affairs give too much to the person who happens to write things down, even if it is written with astonishing and memorable clarity and flair?

Well, I'm not sure, but I do know that I always feel a twinge of thief's guilt when I transcribe an interviewee's unpublished recipe and then print it in this magazine, even though I make attribution to the source. Obviously, I don't intend to argue that the food writer plays a trivial role in the transmission and preservation of traditional food ideas. Actually, I see this anthropological side of food writing as more important than anything else in gastronomy except cooking itself. And it is precisely his anthropological contribution that I prize so highly in Richard Olney's *Simple French Food*.

In the preface, Olney writes: "The fo in this book has been culled from all t corners of France. . . . " And he goes on express "an uneasy sense of the gentle d sipation of regional culinary traditions a the need to succor them."

This praiseworthy impulse—to save t gently dissipating regional traditions France (particularly of Provence, whe he makes his home)—must logically r on Olney's direct experience of those t ditions. Olney learned about simp French food from French people, son how, somewhere. It takes away nothi from the high value of his book—one the best cookbooks produced in an era ri in cookbooks—to say that he owes its co tents to the cooks and cookery authors France, present and past, who have inf enced him. And I do not think that Oln would dispute this point in the slightes

He does, indeed, from time to time, lude to other people who have cooked recorded the food that interests him. Bu think it is fair to say that he does not ma a regular effort to tell readers of *Simp French Food* where he found out abou clearly traditional dish like *Estofinade la rouergatte*, a mixture of salt cod a sliced, boiled potatoes that presumal Olney owes to cooks of the Rouergue d trict. He does go so far as to imply that recipe modifies tradition by substituti salt cod for stockfish: "Stockfish is at t origin of the preparation—but stockf requires a number of days more soaki than salt cod. . . . " But where did Oln acquire his knowledge? Was the dish ready being done with salt cod when first came upon it or did Olney hims make the substitution? It would be nice know at which point the gifted Americ cook-anthropologist intervened and p his own mark on the recipe.

My interest in this question is not the terest, primarily, of a professional curio about Olney's public claim of originalit want to know where tradition ends a Olney begins because I care about the p rity of food ideas, but most of the tim can't tell when he is being a direct cond of recipes gleaned from living informan when he is synthesizing various versions a dish into a version that appeals to him, when he is inventing a dish based, more less, on French practice but branching from it in a personal way. An example the latter possibility is Olney's recipe fo fresh fig, prosciutto, and mint sala Olney is quite open about the novelty adding mint (as a flavoring for a crea sauce and as a garnish) to the traditio combination of figs and ham.

But if he feels free, as indeed he shou to build on French ideas in his own way,

ld be more explicit in telling readers
n he departs from sources and what
e sources are.
realize that I am insisting on a very
standard of disclosure here. But
y has defended the originality of his
in *Simple French Food* with great
city. He told the *Washington Post*, "I
to scare a few plagiarists to death."
ne estimate, the Nelson lawsuit cost
\$250,000. And it has certainly
ed Nelson himself much pain and
ic humiliation. So it seems only fair
Olney should at least give credit to
people who taught him the recipes he
cted and distilled (for all one can tell
most of them, he may simply have
informants' procedures into conven-
l recipe English) and then included in
book he so fiercely defends as his own.
et me be very clear about this. I be-
that the book is in every legal and
l sense Richard Olney's book. I am
suggesting that the sophisticated act
riting down traditional procedures
not eliminate or supervene upon the
s of traditional cooks, for whom we
ern food writers are merely educated
ts.

*mond Sokolov is a writer whose spe-
nterest is the history and preparation
od.*

Johanna's Quail

Quails
cup olive oil
tablespoon tarragon vinegar
Salt
Pepper
tablespoons red currant jelly

Preheat broiler.
Meanwhile marinate quails in a "salad
ressing" stirred together from the oil,
inegar, salt, and pepper.
Set the quails in a roasting pan and
place 6 or 7 inches from the broiler
lame or element.
Turn the birds every five minutes or so
nd baste, each time you turn them,
ith the remaining vinaigrette.
After 15 minutes, swirl the currant
elly into the pan juices. Using tongs,
ip the birds into the jelly and pan
uice mixture to coat both sides. Con-
inue broiling for another 10 minutes,
urning once more. The birds are done
hen they have browned outside and
he juices from the breasts run clear.
Serve immediately. Eat with your
ands; quails are too small to cut prof-
tably with a knife and fork. Steamed
ennel makes a fine side dish.

Yield: 2 servings

Sterling and Silverplate Pattern Matching Service

MORE THAN 2,000 PATTERNS IN STOCK
Substantial Savings over suggested retail prices!
We have thousands of sterling and silverplate patterns in stock—active, inactive and obsolete. Get just the piece or pieces you need at substantial savings today! Many of the patterns we have in stock are not available in retail stores.

EASY TO GET YOUR FREE PRICE LIST
Just tell us your pattern name and manufacturer. We will send you a list of all the pieces we have in your pattern and the price for each. We will notify you when we have additional pieces you might be interested in. No obligation, of course. If you are not sure of your pattern name, ask for our FREE Flatware Pattern Identification Directory.

Jellyfish, Sunny Side Up

Human beings spend thousands of dollars and travel almost as many miles just to lie down in the sun, and they're not the only ones who take some trouble to expose themselves to that fire. Frogs bask, and the hotter the spot the better; sunflowers dutifully follow their namesake all day; night herons perch on treetops to have a more intimate audience with the sun. But one of the champs of sun worship has to be the mangrove jellyfish, *Cassiopeia xamachana*, which has literally turned its life upside down for love of a good photosynthate. Sometime during its evolution, this jellyfish, which carpets the floor of many a Florida mangrove swamp, rolled over onto its bell and then stayed there. It lives in shallow water and its arms, instead of hanging down, drift upward—partly because of the bell's pulsations.

Why go through all these changes for the sun? A number of scientists think it's because of an alga, *Symbiodinium microadriaticum*, that lives symbiotically within the jellyfish. According to Mark Eakin and other researchers at the University of Miami, *C. xamachana* feeds on photosynthates—the excess oxygen and other nutrients produced by the algae when they photosynthesize during the day. In exchange, the algae borrow some nutrients from the jellyfish, get to live in a safe environment—living inside another creature has to be the ultimate way to keep predators from noticing you—and are protected from sudden changes in the environment. If that weren't enough, the jellyfish gently raises its arms to bring the algae several inches closer to the desired object.

The sun is also much desired by photographers, although they turn their backs on it as much as possible. Jeff Foott had his back to the sun and his feet buried in the muck of a central Florida swamp when he leaned over to take this picture. But something stopped him. The lighting wasn't right; he didn't know if he would have a clear shot to the bottom. So Jeff Foott hooked up a strobe to his camera and then went back to his work. He didn't mean any disrespect. But business, after all, is business.—*D.W.*

Communal Roosting (p. 34)

In "Two Principal Strategies in Avi Communal Roosts" (*The American N uralist*, vol. 121, pp. 237–43), P.J. Wea erhead summarizes current hypothes explaining why communal roosting c curs, then suggests a new theory "based the premise that not all individuals parti pate in the roost for the same reason." O theory reviewed in this article, the formation center hypothesis, is present by P. Ward and A. Zahavi in "The Imp tance of Certain Assemblages of Birds 'Information Centres' for Food Findin (*The Ibis*, vol. 115, pp. 517–34). The p dation avoidance hypothesis is discuss in D. Lack's *Ecological Adaptations f Breeding in Birds* (London: Methue 1968). For a good overview of social int actions among animals, including comm nal roosting, see chapter eight of Wittenberger's *Animal Social Behavi* (Boston: Duxbury Press, 1981).

Epiphytes (p. 42)

N. Nadkarni discloses some importa interactions between epiphytes and th host trees in a cover story for *Scien* "Canopy Roots: Convergent Evolution Rainforest Nutrient Cycles" (vol. 214, p 1023–24). Far less technical is D. Perr "An Arboreal Naturalist Explores t Rain Forest's Mysterious Canop (*Smithsonian*, June 1980, pp. 42–52). Benzing, known for his work on vascul epiphytes, writes about them in *The Bi ogy of the Bromeliads* (Eureka: M River Press, Inc., 1980), dealing with e erything from their taxonomy and classi cation through their cellular biolog physiology, nutrition, reproductive bi ogy, and ecology. Mad River Press's a dress is Route 2, Box 151-B, Eureka, C 95501. R. Kirk's *Exploring the Olymp Peninsula* (Seattle: University of Was ington Press, 1980), although written f the layperson, is scientifically accura Kirk briefly reviews the history of t area, covering its geology, plants a wildlife, and places of interest for visito

Rhesus Monkey (p. 62)

The Rhesus Monkey, edited by G. Bourne (New York: Academic Pres

ditional Reading

75), is a two-volume collection of arti-
s providing detailed scientific informa-
n about the animal, but it does not cover
population status. From 1960 to 1980,
pulations of rhesus monkeys in India de-
ned substantially, particularly in the ag-
ultural regions of the north. C.H.
ûthwick, M. F. Siddiqi, and J.R. Op-
nheimer examine this phenomenon in
wer y-Year Changes in Rhesus Mon-
y Populations in Agricultural Areas of
rthern India" (*Ecology*, vol. 64, pp.
4–39). See also "Rhesus Monkey Popu-
ions in India and Nepal: Patterns of
owth, Decline, and Natural Regula-
n," by Southwick et al., chapter 7 of
osocial Mechanisms of Population
gulation, edited by M.N. Cohen, R.S.
alpass, and H.G. Klein (New Haven:
le University Press, pp. 151–70); "Sta-
and Conservation of Rhesus Monkeys
India," by Southwick and Siddiqi, in
rspectives in Primate Biology, edited
P.K. Seth (New Delhi: Today and To-
rrow's Publishers, 1983, pp. 227–36,
tributed in the United States and Can-
a by Scholarly Publications, Houston,
X); "Population Dynamics of Rhesus
onkeys in India," also by Southwick and
ldiqi, in *Primate Conservation,* edited
H.R.H. Prince Rainier III and G.
urne (New York: Academic Press,
77, pp. 339–62); and "Population Pat-
ns and Behavioral Ecology of Rhesus
onkeys (*Macaca mulatta*) in Nepal,"
J. Teas et al., in *The Macaques: Stud-
in Ecology, Behavior and Evolution,*
ted by D.G. Lindburg (New York: Van
ostrand Reinhold, 1980, pp. 247–62).
Conservation and Management of Wild
mate Populations," by Southwick and
D. Blood (*Bioscience,* vol. 29, pp. 233–
), is a short article recommending con-
vation methods to stop the rapid deple-
n of wild primate populations. Finally,
o good books that cover both population
d behavior are A. Jolly's *The Evolution
Primate Behavior* (New York: Macmil-
n Publishing Co., 1985, second edition)
d J.H. Wolfheim's *Primates of the
orld: Distribution, Abundance and
nservation* (Seattle: University of
ashington Press, 1983).

Authors

A visit in the 1970s to a large bla bird roost at Fort Campbell, Kentuc sparked **Patrick J. Weatherhead**'s int est in the communal behavior of bi (page 34). During the past ten years, has done avian research at two sites the Canadian Arctic and at numer sites in the temperate zone. Born in L don, England, but now a Canadi citizen, Weatherhead received a Ph.D. biology from Queen's University Kingston, Ontario, and is an associa professor of biology at Carleton Univ sity in Ottawa. In addition to his search on birds, he has on occasi worked as a professional river guide fo white-water rafting company and has come an avid windsurfer.

The thrill of exploration—of being in
ace where no human has been before
where there is potential for discov-
g new phenomena and interac-
s—is what triggered my canopy re-
ch," writes **Nalini M. Nadkarni**
ge 42). Much of her work is done in
tops, and to reach them she had to
n mountain-climbing techniques.
dkarni, who studied with Charles
er, earned a Ph.D. in 1983 from the
lege of Forest Resources of the Uni-
sity of Washington in Seattle and is
assistant professor of biological sci-
es at the University of California,
ta Barbara. One of her future
jects will use three-dimensional com-
er graphics to map tree crowns and
plant communities they support.
en not swinging through the trees,
ching, or writing grant proposals,
dkarni likes to play squash and bake
ffins.

¡Speak Spanish
(or French, Japanese, Mandarin, and others)
like a diplomat!®

What sort of people need to learn a foreign language as quickly and effectively as possible? *Foreign service personnel,* that's who. Members of America's diplomatic corps are assigned to U.S. embassies abroad, where they must be able to converse fluently in every situation.

Now you can learn to speak Spanish just as these diplomatic personnel do—with the Foreign Service Institute's Programmatic Spanish Course. You'll learn Latin American Spanish recorded by native speakers.

The U.S. Department of State has spent thousands of dollars developing this course. It's by far *the most effective way* to learn Spanish at your own convenience and at your own pace.

The course consists of a series of cassettes and accompanying textbook. Simply follow the spoken and written instructions, listening and repeating. By the end of the course, you'll be learning and speaking entirely in Spanish!

This course turns your cassette player into a "teaching machine." With its unique "programmatic" learning method, you set your own pace – testing yourself, correcting errors, reinforcing accurate responses.

The FSI's Programmatic Spanish Course comes in two volumes, each shipped in a handsome library binder. Order either, or save 10% by ordering both:

☐ **Volume I: Basic.** 12 cassettes (17 hr.), manual, and 464-p. text, $125.
☐ **Volume II: Intermediate.** 8 cassettes (12 hr.), manual, and 614-p. text, $110.

(Conn. and N.Y. residents add sales tax.)

TO ORDER BY PHONE, PLEASE CALL TOLL-FREE NUMBER: **1-800-243-1234.**

To order by mail, clip this ad and send with your name and address, and a check or money order, or charge to your credit card (VISA, MasterCard, AmEx, Diners) by enclosing card number, expiration date, and your signature.

The Foreign Service Institute's Spanish course is unconditionally guaranteed. Try it for three weeks. If you're not convinced it's the fastest, easiest, most painless way to learn Spanish, return it and we'll refund every penny you paid. Order today!

116 courses in 39 other languages also available. Write us for free catalog. Our 12th year.

On his first visit to China in 1975, **Richard Gordon**, (page 52) lived and worked there for two and a half months—long enough to become obsessed with the country. Gordon has since made six trips to China,learned to speak Chinese, and worked in several villages and in a Shanghai factory. He has worked on assignment in China and on the Tibetan Plateau and his photographs have been featured in two *Natural History* stories, "Journey to the Tibetan Plateau" (September 1982) and "Growing Up in a Chinese Village" (November 1984). With Carma Hinton, Gordon has codirected two films: *Stilt Dancers* and *Small Happiness: Women of a Chinese Village*—both have been featured at the Margaret Mead Film Festival. A dropout from the University of Pennsylvania, Gordon hopes to find the time to return and resume his studies.

More than thirty years ago, **Charles Southwick**, left (page 62), was introduced to primate research in Panama while he was studying for his Ph.D. at the University of Wisconsin. Following his postdoctoral work at Oxford University, he conducted more than fifty overseas trips for field research in animal ecology and behavior, primarily in Asia. Southwick taught at Hamilton College, Ohio University, and the Johns Hopkins University, and since 1979, has been a professor of biology at the University of Colorado, where he teaches global ecology and primate studies. His coauthor and colleague of many years in India, **M. Farooq Siddiqi**, right, is an associate professor of geography at Aligarh University. He received his B.A. from Agra University, and his M.A., L.L.B., and Ph.D. from Aligarh University. In addition to his work in primate ecology, Siddiqi is editor of the *Geographer* and a specialist in the economics of village agricultures. Southwick and Siddiqi share keen interests in animal populations, environmental quality, conservation, and human affairs.

"I've got the best job in the world," brags **Jeff Foott** (page 94), a naturalist and photographer. "I can pick out a subject and then go right to the expert and spend more time with him than I would if I were his graduate student." Foott, who grew up in Berkeley, started studying science—in his case marine biology—but found the academic route confining. Working in the field, however, looking "for portraits that have been sculpted over tens of thousands of years," suits him fine. When he comes across a wonderful sight, he goes to the experts. His photograph of an upside-down jellyfish in *The Natural Moment* was shot with a 55-millimeter macro lens.

"Have I got a beach in Spain for you!"

"We rode through an olive grove, down a rocky trail to a secluded beach on these great horses... and went crashing through the ocean. Spain's both more rustic *and* more cosmopolitan than I thought. Puerto Banus outside Marbella is as sophisticated and upscale as anything on the Riviera. Then there are the Canary and Ballearic islands in the Atlantic and the Med... each with its own mood and life."

–Ann Myers
New York, N.Y.

"I know good beaches. I'm from Florida. Spain's are great, with mountains down to the water. Really good seafood... great nightlife. People from all over the world. And it's all so easy ...and inexpensive. I liked everything about Spain. I even heard the other coasts are spectacularly different, with more great beaches. I'm sure I'll get back to find out."

–Peter Schnaedelbach
Ft. Lauderdale, Fla.

"The beaches are where the young people from all over Europe meet... and there's every kind of water sport. Plus the cleanest, bluest water."

Spain. Everything under the sun.

The Sons of India

The informative article by Stanley Freed and Ruth Freed, "One Son Is No Sons" (January 1985) includes what I think is an error. It is stated that the practice of voluntary sterilization after a specified number of sons have been born is responsible for an increased proportion of males in the population of Shanti Nagar, India.

Here is one way to look at the problem: Since the decision to stop having children cannot change the sex of children already born, it cannot change the overall sex ratio. It can, of course, change the relation between sex ratio and family size; smaller sibships will have more males. The size of the sibship is something over which the parents *do* have control. Sterilization might lead to a distorted sex ratio in the sterilized sibships if these constitute an atypical subset of the population. But change the overall sex ratio it won't.

The same false argument, based on stopping further births after an heir is born, has been invoked to explain a reputed excess of males in royal households.

It is necessary to look elsewhere for an explanation of the increased proportion of males in Shanti Nagar.

JAMES F. CROW
Professor of Genetics,
University of Wisconsin,
Madison, Wisconsin

The authors reply

Professor Crow is correct. Sterilization cannot ordinarily affect the proportion of males and females in a population. We regret the error and thank the readers who wrote to us, thereby permitting the prompt publication of this correction. We especially hope to avoid the possibility that our statistical mistake may be interpreted as casting a shadow on the Indian policy of encouraging voluntary sterilization. There was, of course, no such intent. The sex ratio in the village of Shanti Nagar nevertheless typifies the situation in northwestern India, where high male-to-female sex ratios are a longstanding phenomenon. Various explanations have been advanced, including the systematic mistreatment of female children or their possible undernumeration in censuses. A number of causes may be involved, and the problem merits further study.

The major theme of the article remains valid, however—the conflict between governmental attempts to limit family size and the preference for sons as security and support for the elderly. Discussions of population control in India usually emphasize the increasing number of persons who undergo sterilization or who accept family planning. The other side of the coin, the number of surviving children that a couple has at the end of childbearing, receives less attention. Thus people are sometimes surprised that the growth rate of the population has not as yet declined. In an excellent evaluation of the most recent Indian census (1981), which appeared in India's *Economic and Political Weekly*, Pravin Visaria and Leela Visaria write that "the Department of Family Welfare estimates that 42.8 million births had been 'averted' in the 28 years since the [family planning] programme's inception—37 million of them in the decade between the censuses of 1971 and 1981. This may seem a commendable achievement but it failed to make a dent in India's population growth rate during the past decade."

STANLEY A. FREED
RUTH S. FREED

Bat Agony

One can only hope that in some other dimension when Raymond Mendez ("The Natural Moment," October 1984) lies helplessly screaming while being eaten alive by Trinidadian cockroaches, a young bat happens by who has more clearly and justly resolved not only the issue of man's interference in natural systems but also of suffering—and acts more quickly and humanely to alleviate his pain, natural or not.

RUTH A. CAMPO, M.D.
Rutherford, New Jersey

In all my long years of reading *Natural History*, I have never felt the need to write a letter, but I was very moved by the dramatic photograph in the October "Natural Moment." The death of the baby bat presents nature at her grisliest, and I don't

ubt that I would have given the bat the
ne *coup de grâce*. Bravo.

DAVID STEVER
Saint Paul, Minnesota

The photograph is certainly stunning,
d the article is powerful; my criticism is
directed at the skill involved in the pro-
ction of the feature. I just wish someone
d said, wait a minute—do we really
nt to zap them with this one?

JULIA C. SCHIEFFELIN
New York, New York

nsumer Fraud

Tom Eisner's photograph ("The Natu-
Moment," November 1984) of a fly
sing as a spider is quite captivating. The
ry behind the photograph is also rather
eresting, particularly the final para-
ph. There it is disclosed that Mr.
ner placed the fly "in a refrigerator for
hile to slow it down" and later removed
nd took the picture. This would seem to
icate that "The Natural Moment" was
so natural after all. I do not believe
t the fly suffered any injustice; as for
ur readers, however, the subtitle "Con-
ner Fraud" seems to be (in a round-
out way) somewhat appropriate.

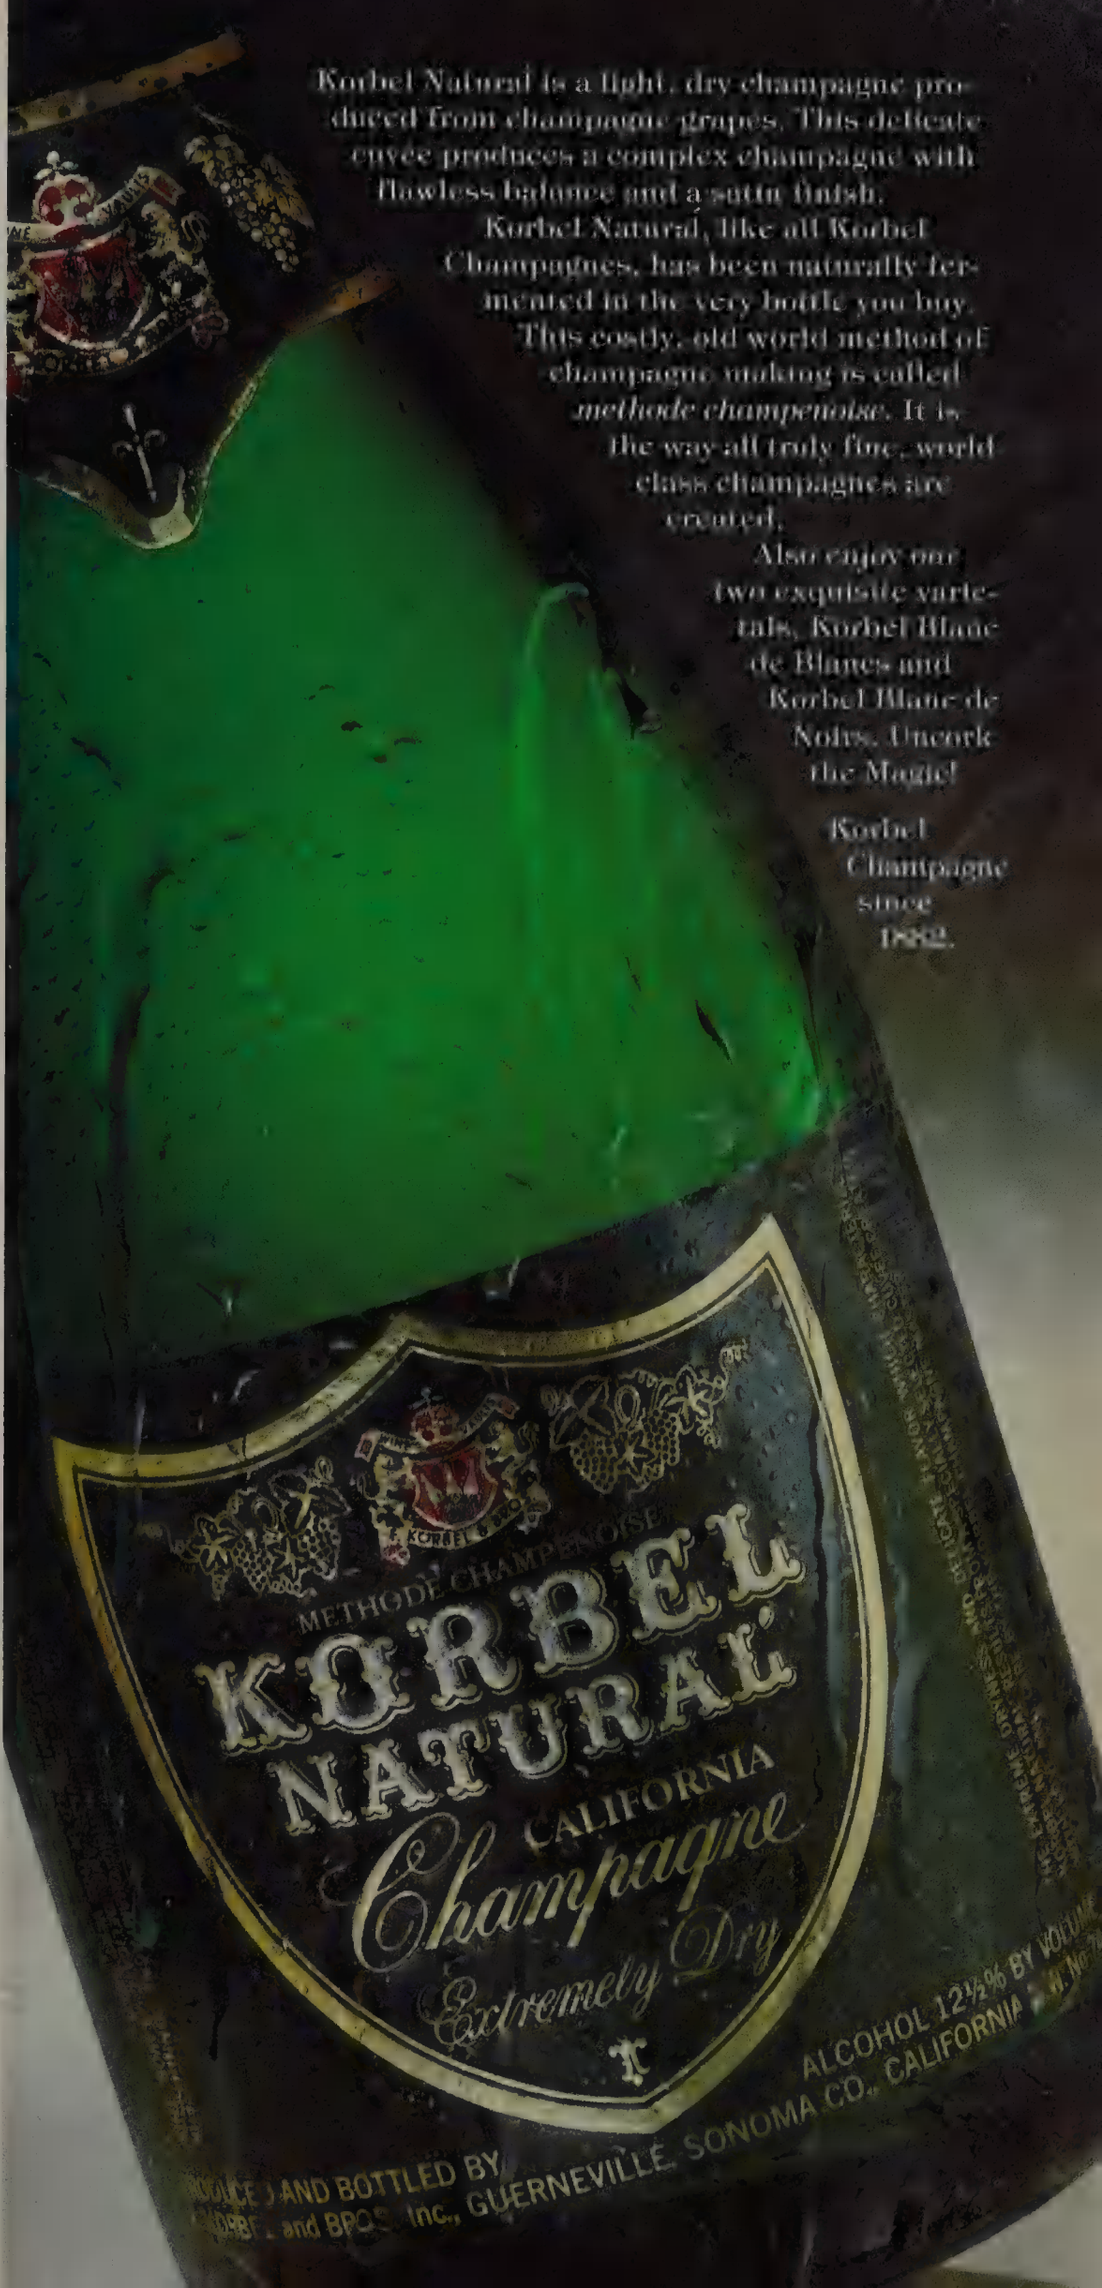
THOMAS GOEBEL
Bolivar, Missouri

e Johnsons' Paradise

I thoroughly enjoyed "Shooting in Par-
se" (December 1984). In the last few
rs, I have collected, read, and enjoyed
tually all of the Johnsons' books.
I am writing in hope that you can an-
er a question—where (exactly) is Lake
radise?

DAVID P. KELLY
Westport, Connecticut

*ke Paradise is in the Gof Sokorte Guda
ter at the top of Mount Marsabit in
thern Kenya. It is accessible by road,
d there is a modest airstrip nearby. Un-
tunately, heavy poaching of elephants
the 1970s severely depleted the ele-
ant herds, and more recently, droughts
ve caused the temporary disappear-
ce of Lake Paradise, which depends on
nfall as its source of water.—D.J.P.*



Korbel Natural is a light, dry champagne produced from champagne grapes. This delicate cuvée produces a complex champagne with flawless balance and a satin finish.
Korbel Natural, like all Korbel Champagnes, has been naturally fermented in the very bottle you buy. This costly, old world method of champagne making is called *methode champenoise*. It is the way all truly fine, world class champagnes are created.
Also enjoy our two exquisite varietals, Korbel Blanc de Blancs and Korbel Blanc de Noirs. Uncork the Magic!
Korbel Champagne since 1882.

Deep inside the Tower of London ies the world's single most valuable object.

TWA Getaway® Vacations. A great way to discover Britain's heritage.

The Imperial State Crown—one f the Crown Jewels—contains no ewer than 3,179 gems.

It is truly priceless.

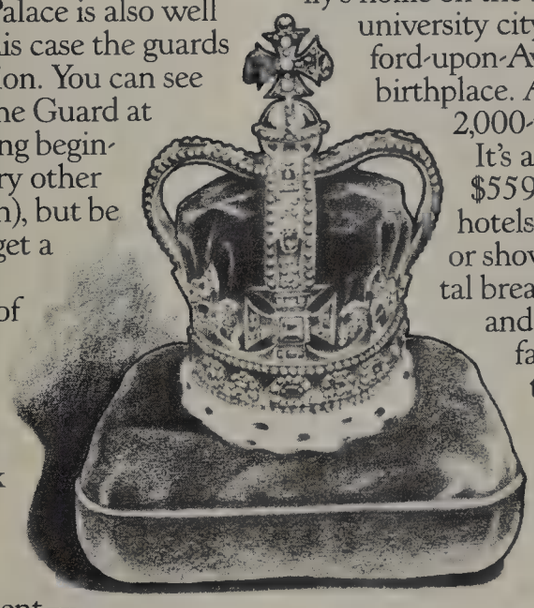
Originally made for Queen Vic- oria's coronation, it's been worn ubsequently by every sovereign on tate occasions. And although the Crown Jewels are on display in the Tower, they are, as you can imagine, ery well guarded. In fact the Chief Warder locks the gates every night in he 700-year-old Ceremony of the Keys.

Buckingham Palace is also well uarded. But in this case the guards re the big attraction. You can see he Changing of the Guard at 1:30 every morning begin- ing in April (every other norning until then), but be here by 11:00 to get a good view.

Luckily, most of London's gems are bit more accessi- ble. Like Big Ben —certainly the most famous clock ower in the world. Down below are the Houses of Parliament— you're welcome to sit in the Strangers' Gallery and watch the proceedings.

Don't leave London—the theatre capital of the world—without taking n a show. In the West End alone here are no fewer than 50 theatres. And tickets cost about half as much as they do on Broadway.

One of the best ways to explore London, or the rest of the country for that matter, is with one of TWA's 11 Getaway Vacations in Britain.



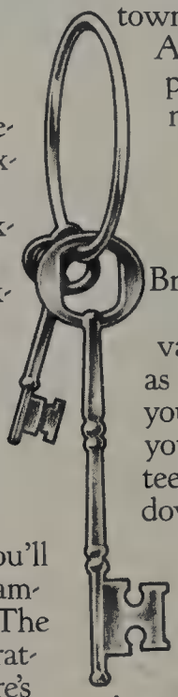
TWA Getaway Vacations. The best of Britain.

Take the 10-day "London Theatre and Countryside" tour, for example. Your five days in London include a sightseeing tour of Buckingham Palace, Big Ben and the Houses of Parliament—even tickets to two West End shows. And you'll have plenty of free time to explore London on your own—and use your discount card that gives you up to 20% off at many shops, clubs, and restaurants.

Then you're off to the countryside by private motorcoach. You'll see Windsor Castle, the Royal Family's home on the River Thames. The university city of Oxford. Stratford-upon-Avon, Shakespeare's birthplace. And Bath, site of a 2,000-year-old Roman spa. It's all for just $429 to $559. That includes hotels with a private bath or shower, daily Continental breakfasts in London, and full English breakfasts and dinners in the countryside.

Super values with TWA's Super Saver Vacations.

See even more of Britain with TWA's Super Saver, "Britain." 14 days in England, Scotland and Wales are just $529 to $629. You'll tour London's Westminster Abbey. Visit Cambridge and York Minster by private motorcoach. Then you're off to Edinburgh, Scotland's capital. The lovely Lake District. And Wales, the land of castles. All hotels have private bath or shower. Daily Continental breakfasts and dinners in many of the towns are also included.



All TWA tour prices are per person, double occupancy, not including airfare.

TWA's airfares are guaranteed.

It's the perfect time to visit Britain. The dollar is stronger than ever. Many of TWA's vacation packages are priced as low as last year. And when you fly TWA, once you buy your ticket your fare is guaranteed not to go up. If airfares go down, you pay the lower fare.

It's also the perfect time to go because Britain's Heritage celebration continues, with special attractions throughout the country. For more information send for your "Britain Heritage" and TWA "Britain" brochures. Then see your travel agent.

Because now, more than ever, the gems of Britain are within your reach.

TWA GETAWAY® VACATIONS.
LEADING THE WAY.

The Flamingo's Smile

Ironically, Darwin often gets credit for Lamarck's great contribution to evolutionary theory

by Stephen Jay Gould

Buffalo Bill played his designated role in reducing the American bison from an estimated population of 60 million to near extinction. In 1867, he and his men killed 4,280 animals in just eight months, under a contract to provide food for railroad crews. His slaughter may have been indiscriminate, but the resulting beef was not wasted. Other despoilers of our natural heritage killed bison with even greater abandon, removed the tongue only (considered a great delicacy in some quarters), and left the rest of the carcass to rot.

Tongues have figured before in the sad annals of human rapacity. The first examples date from the most infamous episodes of gastronomical gluttony—the orgies of Roman emperors. Mr. Stanley, Gilbert's "modern major general," could "quote in elegiacs all the crimes of Heliogabalus" (before demonstrating his mathematical skills, in order to cadge a rhyme, by mastering "peculiarities parabolous" in the study of conic sections). Among his other crimes, the licentious teen-aged emperor presided at banquets featuring plates heaped with flamingo tongues. Suetonius tells us that the emperor Vitellius served a gigantic concoction called the Shield of Minerva and made of parrotfish livers, peacock and pheasant brains, lamprey guts, and flamingo tongues, all "fetched in large ships of war, as far as from the Carpathian sea and the Spanish straights."

Lampreys and parrotfishes (though not without their beauties) have rarely evoked great sympathies. But flamingos, those elegant birds of brilliant red (as their name proclaims), have inspired passionate support from the poets of ancient Rome to the efforts of modern conservationists. In one of his most poignant couplets, Martial castigated the gluttony of his emperors (ca. A.D. 80) by speculating about different scenarios, had the flamingo's tongue been gifted with song like the nightingale's, rather than simple good taste:

Dat mihi penna rubens nomen; sed lingua gulosis
Nostra sapit: quid, si garrula lingua foret?

(My red wing gives me my name, but epicures regard my tongue as tasty. But what if my tongue could sing?)

Most birds have skinny pointed tongues, scarcely fit for an emperor, even in large quantities. The flamingo, much to its later and unanticipated sorrow, evolved a large soft, fleshy tongue. Why?

Flamingos have developed an exceedingly rare mode of feeding, unique among birds and evolved by very few other vertebrates. Their bills are lined with numerous, complex rows of horny lamellae—filters that work like the whalebone plates of giant baleen whales. Flamingos are commonly misportrayed as denizens of lush tropical islands, something amusing to watch while you sip your rum and Coke on the casino veranda. In fact, they dwell in one of the world's harshest habitats—shallow, hypersaline lakes. Few creatures can tolerate the unusual environments of these saline deserts. Those that thrive can, in the absence of competitors, build their populations to enormous numbers. Hypersaline lakes therefore provide predators with ideal conditions for evolving a strategy of filter feeding—few types of potential prey, available in large numbers and at essentially uniform size. *Phoenicopterus ruber*, the greater flamingo (and most familiar species of our zoos and conservation areas in the Bahamas and Bonaire), filters prey in the predominant range of an inch or so—small mollusks crustaceans, and insect larvae, for exam ple. But *Phoeniconaias minor*, the lesse flamingo, has filters sufficiently dense an efficient to segregate cells of blue-gree algae and diatoms with diameters of 0.0 to 0.1 mm.

Flamingos pass water through their bi filters in two ways (as documented in th classic article by Penelope M. Jenkin "The Filter Feeding and Food of Flamin goes," *Philosophical Transactions of th Royal Society of London*, 1957, vol. 240 pp. 401–93): either by swinging thei heads back and forth, permitting the wa ter to flow passively through, or by th usual and more efficient system that in spired the Roman gluttons—an activ pump maintained by a large and powerfu tongue. The tongue fills a large channel i the lower beak. It moves rapidly back an forth, up to four times a second, drawin water through the filters on the backwar pull and expelling it on the forward drive The tongue's surface also sports numerou denticles that scrape the collected foo from the filters (just as whales collect kri from their baleen plates).

The extensive literature on flamingo has highlighted the unique filters in its dis cussion of feeding—and often neglecte another, intimately related featur equally remarkable and long appreciate by the great naturalists. Flamingos fee with their heads upside down. They stan in shallow water and swing their head down to the level of their feet, subtly ad justing the head's position by lengthenin or shortening the S curve of the neck This motion naturally turns the head up side down, and the bills therefore revers their conventional roles in feeding. Th anatomical upper bill of the flamingo lie

Lenox.

First Waltz

A Lenox tribute to American fashion—created under the guidance of our country's leading costume experts.

Individually crafted of fine handpainted porcelain. Available only by reservation.

is 1895, the heart of what was known as e "Gibson Era" or "Gay Nineties." At a society all an elegant young lady awaits the man whom she has promised the first waltz. he is dressed in the height of fashion: pearl oker, ribbed silk gigot sleeves and ostrich-ather fan. Her silk brocade skirt is designed flow gracefully with the whirling motion of e waltz—the popular dance of the day.

First Waltz has been created by Lenox der the guidance of distinguished fashion thorities—Vera Maxwell, renowned fashion signer; Carrie Robbins, award-winning oadway costume designer; Robert Riley, shion Institute of Technology and Matthew ernan, Costume Society of America. This vely figurine represents one of the most portant eras in American fashion and is *storically accurate down to the finest detail.*

A Handcrafted Work of Art

nceived and designed by the artists of nox and created exclusively under their rection by master craftsmen in Japan, each urine is individually crafted of the finest sque porcelain—capturing *extraordinary tail* from the delicate lace-and-ruffle bodice the gently scalloped petticoat.

Skilled artisans paint each piece *by hand,* eating a delicately colored work of art of comparable beauty. And each figurine is nbellished on its base in *pure 24 karat gold* th the title and the world-famous Lenox demark…the symbol of unsurpassed ality and craftsmanship. And, of course, ur satisfaction is *completely guaranteed.*

Available Only Direct from Lenox

st Waltz is available only by reservation rect from Lenox and will not be sold through en the most prestigious dealers or galleries. e original issue price is $95, payable in nvenient monthly installments of $19 with *finance charge.* Each figurine is accom-nied by a Certificate of Authenticity and erature on the history of American fashion.

Since each figurine is individually hand-fted, please allow 6 to 8 weeks for shipment. servations are accepted in strict sequence of ceipt and should be received by March 31, 5. To order, mail the Reservation Application, call **TOLL-FREE 1-800-228-5000** now.

Shown smaller than actual height of 8¼".

© Lenox, Inc. 1985

RESERVATION APPLICATION

Please enter my reservation for *First Waltz* by Lenox. I need send no money now and prefer to pay as follows:

☐ DIRECT. I will be billed for a deposit of $19 in advance of shipment. After shipment, I will be billed for the balance in 4 equal monthly installments of $19* each.

☐ BY CREDIT CARD. Please bill the following credit card account the full amount of $95* after my figurine has been shipped to me.

☐ MasterCard ☐ VISA ☐ American Express

*Plus $2.25 per figurine for shipping and handling. State sales tax will be billed if applicable.

Williamsburg, VA 23187 / (804) 229-1607

Jamestown Festival Park

beneath and serves, functionally, as a lower jaw. The anatomical lower bill stands uppermost, in the position assumed by upper bills in nearly all other birds.

With this curious reversal, we finally come to the theme of this essay: Has this unusual behavior led to any changes of form and, if so, what and how? Darwin's theory, as a statement about adaptation to immediate environments (not general progress or global direction), predicts that form should follow function to establish good fit for a peculiar life style. In short, we might suspect that the flamingo's upper bill, working functionally as a lower jaw, might evolve to approximate, or even mimic, the usual form of a bird's lower jaw (and vice versa for the anatomical lower, and functionally upper, beak). Has such a change occurred?

Such curious exceptions provide our best tests for general rules. Nature harbors a large suite of oddities so special that we scarcely know what to predict. But, in this case, we encounter a precise reversal of anatomy and usual function—leading to a definite expectation: do upside-dow animals reorient the form of their bodie to a new function when current behavio and conventional anatomy conflict?

We may begin by sparing the usual por tification (but only for a while) and lookin at a picture (on the old idea that we gai thereby at least a thousand words, or abou one-third my assigned length—though usually manage to exceed the limit). If thi picture (below) excites a vague feeling o familiarity slightly awry, your perception are acute, but ride with me for a while.

We seem to see a long-necked swa with a broad smile. But look carefully, fo details betray this impossible beast. It mouth opens *above* the eyes; its feather run the wrong way; and where are its legs I next show you the celebrated original i its proper orientation (and with the legs re stored)—the flamingo from J.J. Audu bon's *Birds of America*, and a sure entr on anyone's hit parade of most famous pic tures in natural history.

This dramatic perceptual switch fron happy swan to haughty flamingo recall

Does this strange bird seem familiar? (See page 10)

Discover the wonders of the world's most complex, most miraculous organism.

The Human Body

Begin with the first volume in this fascinating series...

THE BRAIN

YOURS TO EXAMINE FOR 10 DAYS FREE

No obligation to buy a thing.

Torstar Books invites you to embark on an extraordinary voyage of discovery—a journey through the frontiers of science, medicine, and the most awesome of all creations: THE HUMAN BODY.

A richly illustrated library

The volumes in THE HUMAN BODY library are more exciting than any adventure novel, because the story they tell is true. In thousands of never-before-published photos, see-through diagrams and drawings you'll watch the body at work: you'll see what the heart looks like—from inside—as it pumps 5-6 quarts of blood a minute ... watch "enkephalins," the body's natural painkiller, speed into action to eliminate pain ... and learn how all the parts of your body work *together* to make you the person you are.

Filled with the latest medical breakthroughs and life prolonging discoveries

Peer through the scanning electron microscope to see how cancer cells insinuate themselves directly into the blood stream. Learn about the incredible contributions computers are making to medicine today. Share the latest news on interferon, the miracle drug which promises a critical breakthrough in our fight against cancer, viruses, chicken pox, even the common cold.

An important new resource

THE HUMAN BODY is the most comprehensive and richly illustrated reference on all the medical sciences available today. A source not only for general knowledge and fascinating reading but as a reliable and professional authority for term papers, reports, and classroom presentations. A series that every member of your family will benefit from.

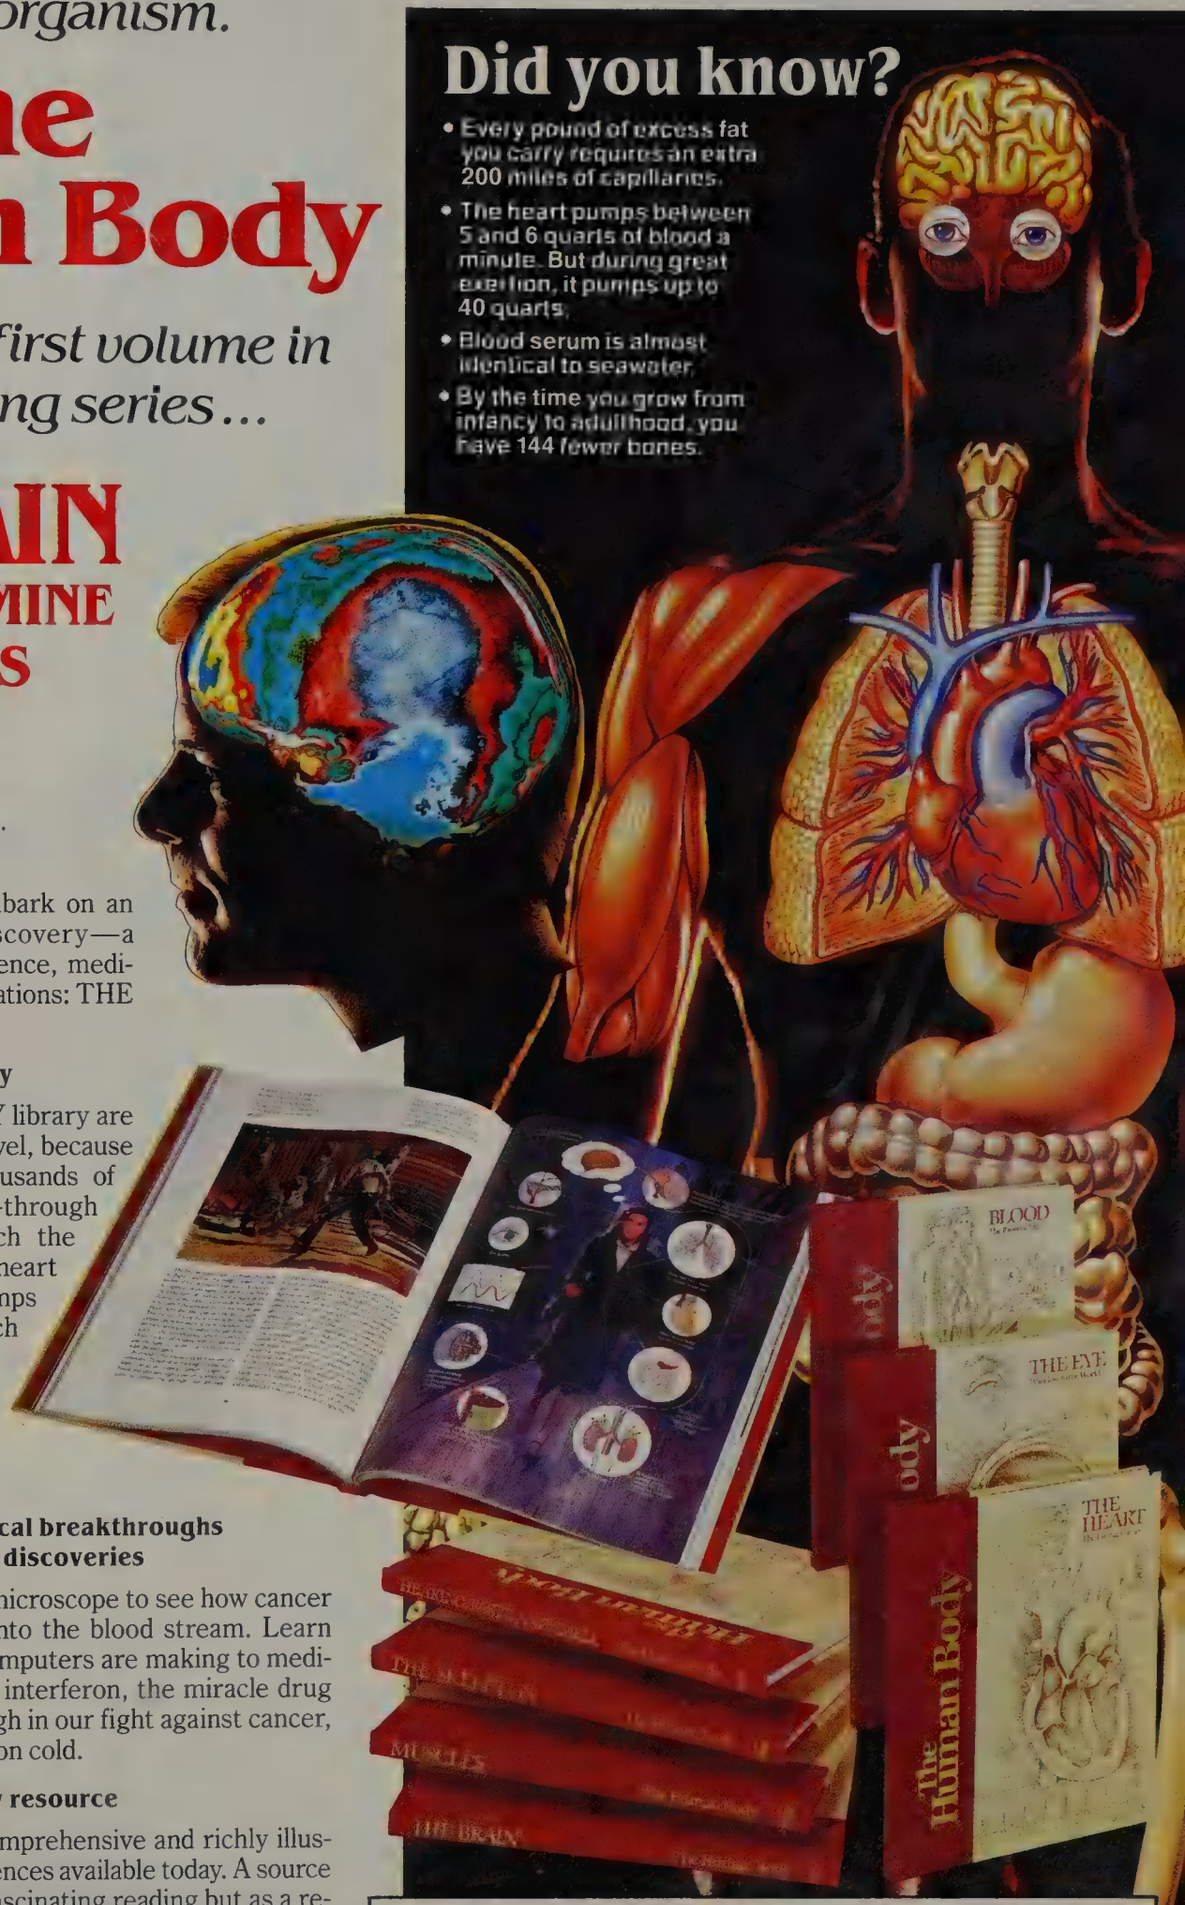
To receive your FREE preview copy of THE BRAIN and your FREE digital thermometer, mail the attached card today!

If postcard is missing, send your name and address to TORSTAR BOOKS, P.O. Box 10669, Des Moines, Iowa 50336. Ask for THE BRAIN to examine for 10 days FREE.

TORSTAR BOOKS

Did you know?

- Every pound of excess fat you carry requires an extra 200 miles of capillaries.
- The heart pumps between 5 and 6 quarts of blood a minute. But during great exertion, it pumps up to 40 quarts.
- Blood serum is almost identical to seawater.
- By the time you grow from infancy to adulthood, you have 144 fewer bones.



Act now and receive a digital thermometer FREE

- Electronic digital thermometer safe for adults and children.
- Quick and accurate body temperature readings in only 60 seconds. Over 1,000 hours of battery life.
- Buzzer sounds when temperature level has been reached.

Russia's Mighty Volga River Cruise

Experience Salen Lindblad's Expedition Cruising. It's Five Star adventure exploring the little known travel gems.

This summer, discover Russia cruising along her historic Volga and Don Rivers. Explore former Cossack outposts; the ancient capitals of Soviet Georgia; as well as Moscow and Leningrad. Your river vessel is modern, yacht-like, with wide picture windows. See Russia beyond the usual tourist paths.

any standard item in the psychological arsenal of optical illusion—particularly the young, well-dressed lady looking away who becomes the old hag in profile. In fact, any accurately executed picture of a flamingo produces the same jolting effect when viewed upside down (I have checked all historically important portraits)—and for an obvious reason. The jaws have evolved to fit their reversed function. The flamingo's upper jaw does look like a typical bird's lower bill, and we therefore see the upside-down flamingo, not as an absurdity, but as an only slightly odd, swanlike bird.

The morphological alterations go far beyond the changes in external form that produce such a stunning perceptual shif from upright flamingo to inverted "swan." But note first the peculiar curve of the beak itself. The flamingo's bill project out from its face, but then makes a sharp angular turn, producing the pronounced hump that looks like a trough (and works like one) when inverted for feeding. Some Near Eastern peoples call flamingos "cam els of the sea," not because the inclined bil recalls the hump on a camel's back, bu because it mimics the bend of the nose that imparts an inappropriate (but un shakable) impression of haughtiness to both animals (see my essay on the history of Mickey Mouse and the messages acci dentally conveyed by facial features of an

The flamingo from Audubon's Birds of America AMNH

nals, May 1979). Turned upside down, ne hump becomes a grin as a smiling swan" replaces the haughty flamingo.

The bills are elaborately adapted to neir reversed roles, not simply bent in the niddle for proper reorientation. First, relative sizes are rearranged to complement ne shapes. The upper bill is small and nallow, the lower deep and massive. (In nost birds, the smaller lower bill moves up nd down against the larger upper beak.) econd, the flamingo's lower bill (functionlly upper in feeding) has evolved unusual igidity. The bones of each half (or ramus, n technical parlance) are tightly fused, and he rami themselves are then bonded extenively to each other. The lower bill is nassive and well braced. The tongue runs ore and aft in a deep trough cut into the ower jaw. (Remember that filter feeding ets the coordinating theme for all these hanges—the upside-down feeding posure, the attendant alteration in size and hape of the bills, and the fat tongue that nce almost sealed the flamingo's fate.) Third, in most species of flamingo, the maller upper jaw slots into a receiving pace on the larger lower jaw, a reversal of he usual convention—lower jaw moving p and fitting into a larger upper bill.

These complex, coordinated changes nake a persuasive case, but they leave a nissing piece recognized as the key to flaningo peculiarities ever since Menippus ecorded the first-preserved speculation early 300 years before Martial's plea: are novements also reversed to match the inersion of form?

In most birds (and mammals, including umans), the upper jaw fuses rigidly to he skull; chewing, biting, and shouting nove the mobile lower jaw against this table brace. If reversed feeding has conerted the flamingo's upper jaw into a vorking lower jaw in size and shape, then ve must predict that, contrary to all anaomical custom, this upper beak should nove up and down against a rigid lower aw. The flamingo, in short, should feed by aising and lowering its upper jaw.

With great credit to the clear thinking f our finest naturalists, I noted with pleaure in my readings that this central quesion has been continually posed as paranount for more than two thousand ears—by scientists of many cultures and nrough all the vicissitudes of theory and ractice that have marked the history of iology. Georges Buffon, the greatest of ll synoptic naturalists, began his midighteenth century essay on the flamingo y admitting the fame of its red color, vhile maintaining that the odd form of its eak posed a problem of even greater inerest: "This fiery color is not the only

SHOW YOUR KIDS HOW 2x4s ARE MADE.

Turning a two ton hunk of Douglas fir into over 300 board feet of 2x4s is a sight to behold, and your family is hereby invited to behold it.

We'd like to give you all a comprehensive tour of one of our lumber mills or plywood plants—from debarking to computerized laser sawing to waste processing to a Q&A session with a mill superintendent.

We offer you tours like this because we want you to understand that our mills and plants and logging sites serve your interests as well as ours.

And because we're proud of them.

Flamingo, by Nehemiah Grew, 1681

striking character displayed by this bird. Its beak has an extraordinary form, the upper bill flattened and strongly bent at its midpoint, the lower thick and well set, like a large spoon." In short, and in his own lovely tongue—*"une figure d'un beau bizarre et d'une forme distinguée."*

Then, tracing the question right back to Menippus, Buffon states the *primum desideratum* of flamingo studies—"to know if, in this singular beak, it is (as many naturalists have said) the upper part that moves, while the lower remains fixed and motionless." The first extensive and explicit commentary had been offered in 1681 by Nehemiah Grew, the great English naturalist, known primarily for his early microscopical studies of plants. Cataloging the collections of the Royal Society—in his *Musaeum Regalis Societatis or a catalogue and description of the natural and artificial rarities belonging to the Royal Society and preserved at Gresham Colledge, whereunto is subjoyned the comparative anatomy of stomachs and guts*—he encountered a lone flamingo and stated: "that wherein he is most remarkable, is his bill." Grew then suspected that the oddities would all be resolved if the upper beak moved against a stationary lower jaw. He stated that the "shape and bigness of the upper beak (which here, contrary to what it is in all other birds that I have seen, is thinner and far less than the nether) speaks it to be more fit for motion and to make the appulse and the nether to receive it."

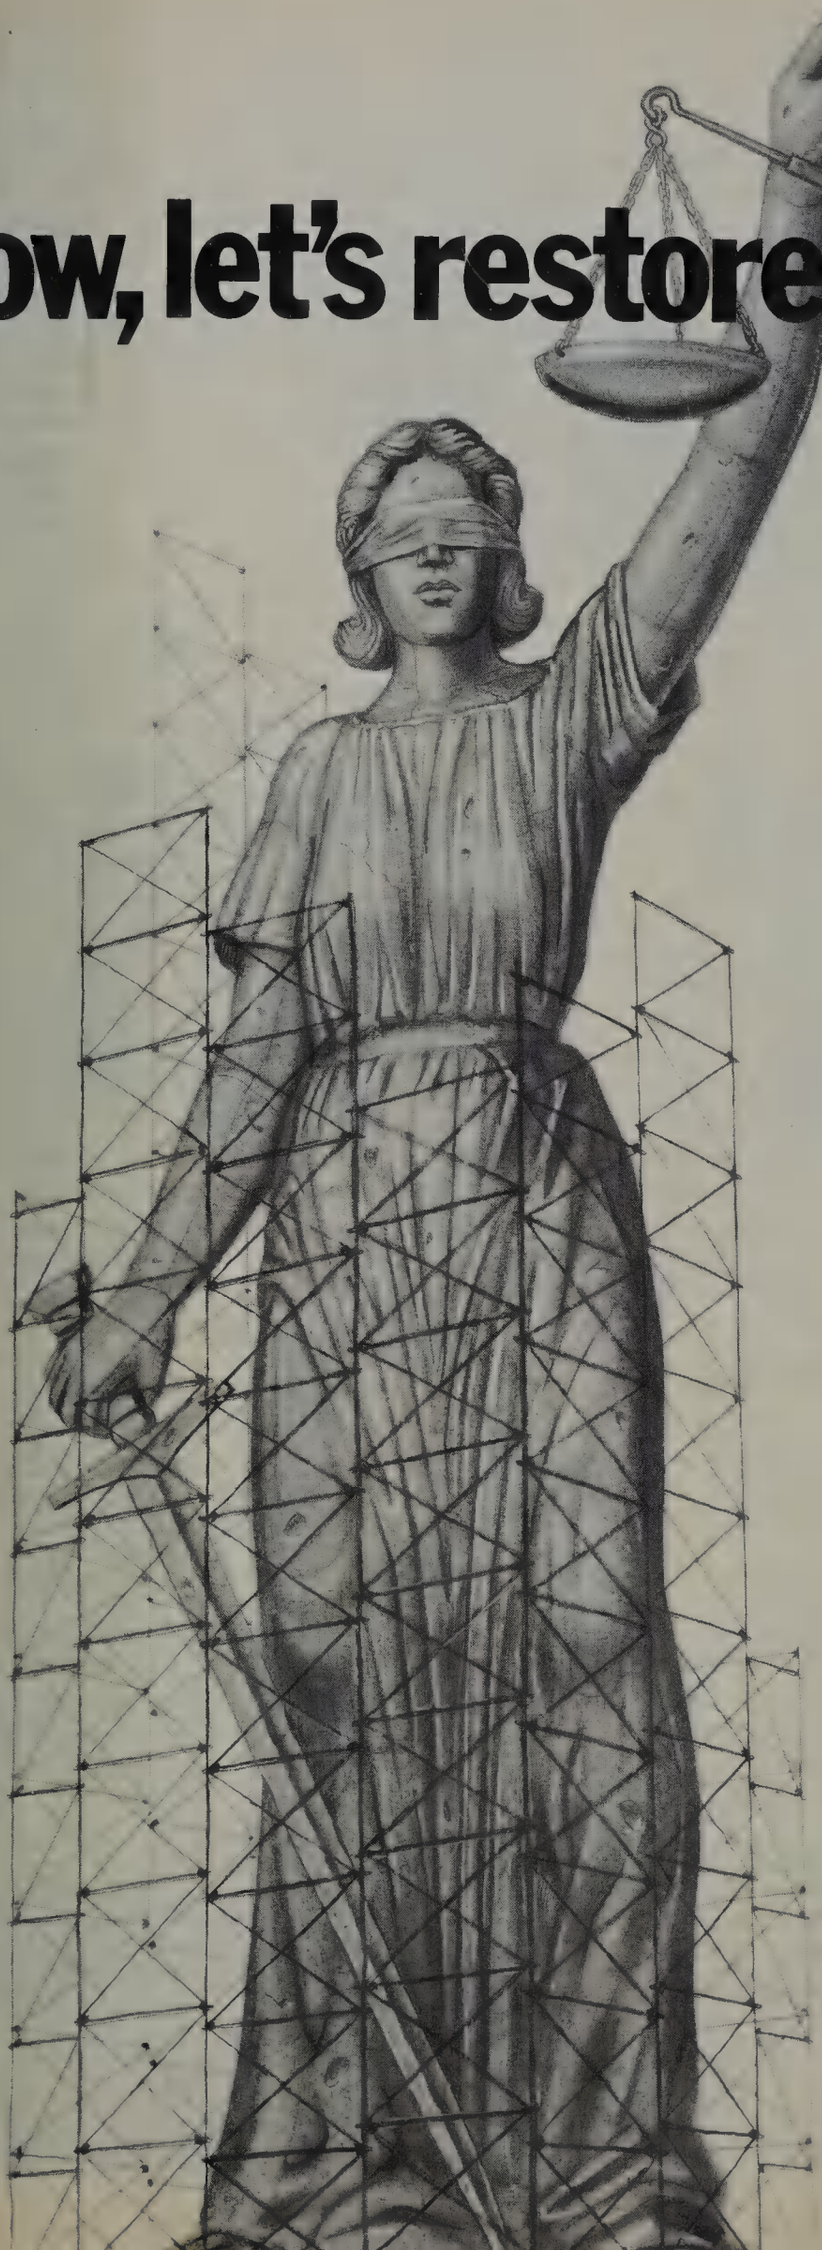
The question was not fully resolved until Jenkin published her comprehensive paper in 1957, affirming with hard data the suspicions and good judgment of Menippus, Grew, and Buffon. In fact, flamingos have developed a highly mobile ball and socket joint between upper and lower jaws. The beaks therefore have unusual mobility, and each can move independently. In preening, either the upper or lower jaw may be opened and operat against the other. But, in feeding, the u per jaw usually drops and raises agains stationary lower jaw—just as the gr naturalists had always expected.

The correspondence is complete— form *and* motion. The shapes are ov turned by bending, the sizes reversed, t slotting inverted, the buttressing tra posed. The action, too, is topsy-turvy. peculiar reversal in behavior has eng dered a complex inversion of form. Evo tion as adaptation to particular modes life—Darwin's vision—gains streng from an extreme test imposed by life tirely upside down.

But do flamingos just provide a fun example or do they symbolize a gener ity? What about other animals that l upside down? Consider another animal shallow West Indian waters, the invert jellyfish, *Cassiopeia xamachana* (the orthodox trivial name honors the Nat American designation for the island of maica).

Cassiopeia is an unconventional jel fish in many ways. It grows neither m ginal tentacles nor central mouth. Instea eight fleshy and complexly branch "oral arms" (so called because each c tains a separate mouth) emerge from short and stout central stalk, itself tached to a usual jellyfish umbrella wit difference. The oral arms are cramm with symbiotic algal cells, a possible ada tive impetus for their elaborate branchi (to provide light-capturing surface the photosynthetic symbionts). Each o arm harbors about forty oral vesicles hollow sacs connected with the feedi canals and containing bags of nema cysts, or stinging cells, at their tips. T vesicles shoot their nematocysts at pr (mostly small crustaceans) in strings mucus; the strings with their attached a paralyzed victims are then pulled into t oral mouths. (Yes, I was as amused

Now, let's restore Civil Justice.



Year after year, our civil justice system has become slower. More costly. Less fair to the very people it was meant to help.

We all pay the price. Some of us pay in the frustration of waiting for a case to end, or by seeing a settlement eaten away by legal costs. All of us pay in the form of higher taxes and insurance premiums.

Experts agree on the urgent need for civil justice repair. Chief Justice Burger has criticized "the high cost of legal services and the slow pace of justice." Derek Bok, president of Harvard and former dean of Harvard Law, has called our legal system "the most expensive in the world."

A 1984 Rand Corporation study of thousands of asbestos-related lawsuits shows how serious the crisis has become. Cases closed took an average two years and eight months, with 11 percent taking six years. How much money went to asbestos victims? Only 37 percent of the expenses and compensation paid by defendants and insurers. The other 63 percent went to pay litigation costs.

Can anything be done? We think it can.

We're the Insurance Information Institute. Our members, property and casualty insurance companies, are vitally involved in this issue. They've joined with others–doctors, lawyers, government officials, business leaders–in coalitions of concerned citizens. Together, they're developing new solutions. In many states, their ideas are being translated into action.

Our latest report, *The Civil Justice Crisis,* examines the reforms now being proposed. It tells how you can get involved. We'd like you to have a copy, free of charge.

INTERNATIONAL EXPEDITIONS INC

some of you by the redundant "oral mouth"—the zoological equivalent of pizza pie or AC current. This clumsy phrase arises as unfelicitous fallout from a prior decision to call the appendages "oral arms"—as a shortcut for "mouths of the oral arms.")

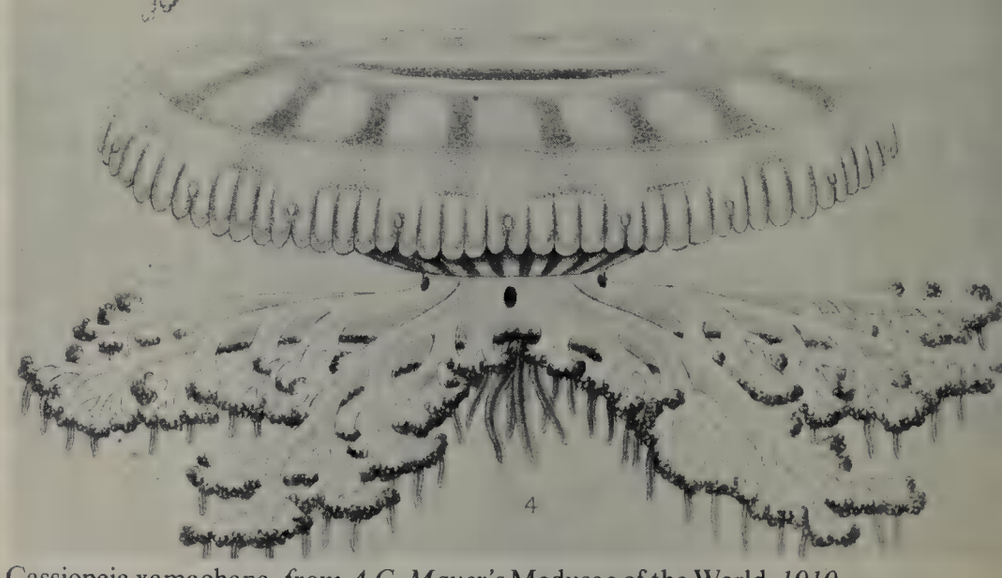
Cassiopeia's unusual anatomy matches its unconventional orientation and style of life. Ordinary, self-respecting jellyfish swim actively with their umbrellas uppermost and their arms and tentacles below. *Cassiopeia* lies stationary on the bottom of shallow ponds and coastal areas—upside down. The top of its umbrella hugs the sediment and the oral arms wave above, waiting for small crustaceans to enter their orbit. Sailors at Fort Jefferson in the Tortugas, where *Cassiopeia* lined the docks, called them "moss cakes." (Since *Cassiopeia* can give a nasty sting, and since men in blue usually spice their language to match the stimulus, I wonder what the sailors really called them. But H.F. Perkins, writing in 1908 on the anatomy of *Cassiopeia*, didn't tell us.)

The umbrella of *Cassiopeia* recalls the flamingo's jaw in its adaptation to reversed life. The umbrella of ordinary jellyfish has a smoothly convex upper surface, as hydrodynamic efficiency dictates. But the upper surface of *Cassiopeia*'s umbrella (its functional lower surface for life upside down) is markedly *concave*—well suited to serve as a cupping device for gripping and holding the substrate.

Cassiopeia has made a second intriguing change for its unusual reversed life. Most jellyfish move through the water by contracting rings of concentric muscles that circle the outer portion of the umbrella. In *Cassiopeia*, one of these muscle rings has been raised and accentuated, forming a continuous circular band surrounding the inner concavity. This raised rim operates together with the concave surface to form an efficient suction cu that keeps the "head" of this jellyfish in it proper position on the bottom. (*Cassio peia* can still swim, albeit weakly and ine ficiently, in the conventional manner. dislodged from the bottom, it will tur over and swim for a few pulsations befor settling down again.) Some scientists hav also suggested that the pulsating contrac tions of the concentric muscles, ordinaril used in swimming, serve other importan functions in *Cassiopeia*'s attached, up side-down position—maintaining connec tion with the substrate by pushing the an mal down and moving water currents wit potential prey toward the oral arms. Bu these reasonable proposals have not bee properly tested.

Thus, flamingos and *Cassiopeia*, tw animals that could scarcely differ more i design and evolutionary history, share th common feature of feeding upside down As a general message amidst the particu lars, they have both redesigned conven tional anatomy to match reversed life style The flamingo's upper bill has change radically in size, shape, and motion to loo and work like the lower beak of most birds The structural top of *Cassiopeia*'s um brella has inverted its shape, all the bette to work properly as an ecological bottom

Adaptation has a wonderful power to a ter an anatomical design, widespread an stable among thousands of species, for th reversed requirements of an odd life styl assumed by one or a few aberrant forms Yet we should not conclude that such Dar winian adaptation to local environment has unconstrained power to design theo retically optimum shapes for all situa tions. Natural selection, as a historica process, can only work with material avai able—in these cases the conventional de signs evolved for ordinary life. The resul ing imperfections and odd solutions cobbled together from parts on hand



Cassiopeia xamachana, *from A.G. Mayer's* Medusae of the World, *1910*

George Lupo

Martha Woodward (2)

If this is what a beginner can do with the Nikon FG, imagine what you could do with a little practice.

Recently, we recruited a group of eople who were novices at 35mm LR photography, handed them Nikon G's, and set them loose in California. Their results didn't surprise us in e least.

e Programmed FG

Because we designed the FG to be so simple that a beginner could take great pictures with it from day one.

Yet we engineered so many sophisticated systems into the FG that it's perfect for a serious photographer, too.

You see, the FG is a camera that gives you as much or as little automation as you want.

In the programmed mode, just focus and shoot. In automatic, you can control depth of field by choosing an aperture while the camera selects the appropriate shutter speed. And in manual, you can set both for complete creative control.

What's more, with the FG's extraordinary through-the-lens flash metering system and the optional SB-15 Speedlight, even the most complex flash pictures become simplicity itself.

So try out an FG at your Nikon dealer.

Because no matter how terrific you think these pictures are, there's nowhere to go from here but up.

Nikon
We take the world's greatest pictures.®

record a process that unfolds in time fro unsuited antecedents, not the work of perfect architect creating *ab nihilo*. *Ca siopeia* co-opts a band of muscles orc narily used in swimming and forms raised rim to grasp the substrate. Flami gos bend their bill in a curious hump as th only topological solution to a new orient tion.

These adaptations to life upside dow are not just funny facts. They help us comprehend the solution to a major ar classical dilemma of evolutionary theo (hence my decision to unite them in th essay). We can easily understand how fl mingos and *Cassiopeia* work; their u usual features do fit them for their unco ventional lives. But how do these oc structures arise if evolution must proce through intermediate steps? (No one w seriously suggest that the first prot flamingo, turning its head upside dow then produced offspring with a comple set of complex adaptations to reverse life.)

In pre-Darwinian years of the earl nineteenth century, when evolution wa new, and when early exponents of this ra ical idea were trying to work out its ram fying implications, two schools emerge and carried out an interesting (and large forgotten) struggle until Darwin resolve their debate. All admitted the good that usually exists between form and fun tion—adaptation in its static, nonhisto cal meaning. Structuralists, like Etienn Geoffroy Saint-Hilaire, argued that for must change first and then find its fun tion. Functionalists, like Jean Baptiste L marck, held that organisms must fir adopt a different mode of life to trigg some sort of pressure for a subsequent altered form.

The nature of this "pressure" inspire another famous (and better remembere but no more important) debate. Lamarc held that organisms responded creative to the needs imposed by their enviro ments and then passed the changes d rectly to offspring—"inheritance of a quired characters" in the usual jargo Darwin argued that environments do n impose their adaptive pressures directl Rather, those organisms fortuitously var ing in directions better suited to local env ronments leave more surviving offsprin by a process of natural selection.

Since Darwin won this argument abou the nature of signals that pass from env ronment to organism, Lamarck has bee eclipsed and still, despite many efforts b historians to set the record straight, su fers from an imposed reputation as a los not worth taking seriously for any of h ideas.

But Lamarck had the right answer (the me as Darwin's) to the larger dispute be- den structuralists and functionalists. le only proposed the wrong mechanism r how environment gets its message to ganisms.) Geoffroy's structuralist solu- on contains an obvious (and probably fa- lly unresolvable) dilemma. If structure anges first, according to unknown "laws form," and then finds the environment st suited its altered state, then how can ecise adaptation arise? We might allow at some very basic and general change uld precede any functional meaning or lvantage—an animal might, for exam- e, get larger and then exploit the inher- it advantages of increased size. But can e seriously believe that something so mplex, so multifarious, and so inti- ately suited for an unusual ecology as ie flamingo's bill might arise before the ct and without relationship to its useful- ess—permitting the flamingo to discover ly later how nicely such a beak worked pside down?

Lamarck's functionalist solution has an egant simplicity accepted by nearly all volutionists today (but usually attributed Darwin, who also supported it. How- ver much I revere Darwin, I want to ad- ance a plea for recognizing this basic rinciple as Lamarck's primary contribu- on. It does not appear as an incidental otnote in Lamarck's *Philosophie zoo- gique* of 1809, but as a central theme of is book. Lamarck knew exactly what he as arguing and why). Lamarck simply cognized that change of behavior must recede alteration of form. An organism nters a new environment with its old form uited to other styles of life. This behav- ral innovation establishes a discordance etween new function and inherited rm—an impetus to change (by creative sponse and direct inheritance for La- arck, by natural selection for Darwin). he protoflamingo first inverts its normal ill—and it doesn't work very well. The roto-*Cassiopeia* turns over, but its con- ex umbrella doesn't clutch the substrate. amarck wrote:

> is not the shape either of the body or its arts, which gives rise to the habits of ani- als and their mode of life; but it is, on the ontrary, the habits, mode of life, and all ie other influences of the environment, hich have in course of time built up the iape of the body and of the parts of ani- als.

The direct evidence for Lamarck's solu- on cannot emerge from such "com- leted" adaptations as the flamingo's eak or *Cassiopeia*'s umbrella—though ie inference even here becomes quite ompelling (for why should flamingos,

uniquely among birds, develop such a pe culiar beak if not to exploit their chose odd environment). We must catch the pr cess at its beginning stages—by findin upside-down animals that have already a tered their behavior but not their form.

African catfishes of the famil Mochokidae, for example, include severa species that characteristically swim up side down. Behavior has already change radically, and we have even obtained goo hints about the triggers in some case (*Synodontis nigriventris*, for example eats algae by grazing the undersides o leaves on water-dwelling plants.) But form has altered scarcely, if at all. A few specie have reversed the usual pattern of crypti coloration for fish swimming near the su face. The light bellies of most fish rende them invisible to predators looking u through the water into sunlight above. Bu *S. nigriventris*, as its name (black belly implies, is dark on its anatomical unde side and light on its structural top. Sinc this fish swims upside down, the light sid lies below, as usual. Yet, beyond thi switch in color, most upside-down mocho kids look just like their upright relatives Size, shape, and position of fins have no changed. The trigger (presumably recent is behavioral. We shall wait to see wha changes in form might still ensue.

As a final point, readers might acknow edge my argument but dismiss the exam ples as trivial or peripheral. We all lov flamingos, and *Cassiopeia* might pric our interest (our bodies too, if we get in th way). Mochokids are amusing in aquaria But can we view life upside down as an more than a funny little corner of natura history? All my examples are dead-end ad aptations of a few species; can turning up side down lead to anything fundamenta and expansive?

As an important illustration from his tory (though almost surely an incorrec idea), life upside down once compelled at tention as a leading speculation for th origin of vertebrates—the "worm tha turned" theory, so to speak. Annelids an arthropods, the most complex of seg mented invertebrates, develop ventra (bottom) nerve cords; the esophagu pierces the nerve cords and connects a even more ventral mouth to a central al mentary (gut) canal lying above the nerv cords. In vertebrates, the major nerve cor runs fore and aft in a dorsal (top) position and the alimentary canal, includin mouth and esophagus, lies entirely below

These two designs seem quite in compatible and unrelated. But, and ironi cally in the context of my contrast be tween structural and functional views, th greatest of all structuralists, Geoffro

int-Hilaire himself, noted that an anne- turned on its back would look more n a bit like a vertebrate—for the ven- l nerve cord would then become dorsal d lie above the alimentary canal. In ving one problem, others emerge: the uth now lies topmost on the inverted rm. Geoffroy suggested, as an ad hoc ution straining credulity, that the old uth and nerve-piercing esophagus sim- disappeared and that an entirely new ening (the vertebrate mouth) developed low the dorsal nerve cord, connecting ectly with the gut canal and not pierc- the nervous system. (So many other fferences plague the comparison—lack any annelid structure resembling the tocord or gill slits of vertebrates, funda- ental disparities in embryological devel- ment between the two groups, for exam- e—that the worm theory never mmanded general assent, though it re- ained a leading contender for nearly a ntury.)

Geoffroy never intended his compari- n of vertebrate with inverted worm as an olutionary speculation, but only as a uctural comparison to buttress his re- arkable theory that all animals shared a mmon architectural plan. (He also ar- ed that the segments of an insect's ex- nal skeleton matched our internal ver- brae—and that insects literally lived thin their own vertebrae. This compari- n compelled the additional and astonish- conclusion, forthrightly maintained by offroy, that insect legs are vertebrate s.)

Geoffroy also did not advance his com- rison as a functional hypothesis about aptation—he did not argue (as La- arck might have done) that a worm's in- vative behavior (in turning over) trig- red an adaptive pressure for redesign. uite the contrary: he contended, as a ucturalist, that belly and back are eaningless terms of human invention to scribe a superficial orientation utterly thout significance to what really mat- s—abstract structural laws of form and rmitted pathways of change.

Today, we reject Geoffroy's speculation ong with his approach to form and func- n. Life upside down affirms Lamarck's im that substantial change in morphol- y usually arises as a consequence of be- vioral triggers. The famous fourteenth- ntury motto of that upstart institution, ew College, Oxford, seems to embody essential truth about history as well as nduct: Manners Makyth Man.

ephen Jay Gould teaches biology, geol- y, and the history of science at Harvard niversity.

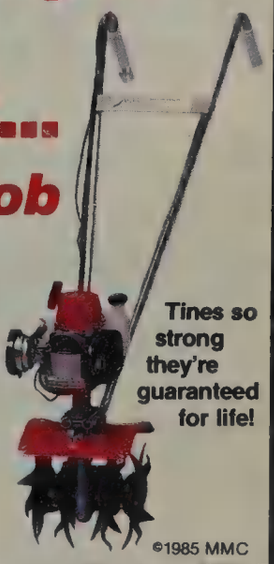
SUBURBAN GARDENERS

Don't Buy A BIG TILLER...

for a small job



Tines so strong they're guaranteed for life!

If your garden is an acre or less, *hire* somebody to plow it once a year . . . and *buy* a Mantis-20 for yourself. Mantis tills and weeds a practical 6" to 9" wide, turns on a dime and *weighs only 20 pounds!* Simply turning a 300-pound tiller in a backyard garden is a challenge.

Most big tillers were designed to just till (but many now offer clumsy "add-on" attachments as an attempt to justify their high cost). The Mantis was *designed from the beginning* to precisely match a small, powerful engine to a variety of *useful* attachments for your yard and garden.

Most big tillers cost an arm and a leg. The Mantis-20 is a tough, durable, precision instrument . . . yet it *costs* a fraction of what you'll pay for a big tiller.

3-WEEK TRIAL

Most machines are *partially* covered for 90 days to a year. Mantis has a *Lifetime Warranty* on the tines, a *Lifetime Replacement* agreement on the engine. Best of all, you get a *3-Week In-Your Garden Trial* (if you don't like it we'll buy it back for every penny you paid!).

Superheroes in the Doll Corner

Play patterns and fantasies help young children define themselves as boys or girls

by Vivian Gussin Paley

Kindergarten is a triumph of sexual self-stereotyping. No amount of adult subterfuge or propaganda deflects the five-year-old's passion for segregation by sex. Children of this age think they have invented the differences between boys and girls and, as with any new invention, must prove that it works. The doll corner is often the best place to collect evidence. It is not simply a place to play; it is a stronghold against ambiguity.

When the children separate by sex, I, the teacher, am more often on the girls' side. We move at the same pace and reach for the same activities, while the boys barricade themselves in the blocks, periodically making forays into female territory.

The boys have been trying to leave the doll corner since they came to kindergarten. They are superheroes now—or feel they should be. The girls do not object to superheroes or robbers in the doll corner as long as they play the way girls play.

Domestic play looks remarkably alike for both sexes at age three. Costumes representing male and female roles are casually exchanged. Everyone cooks and eats pretend food together. Mother, father, and baby are the primary actors, but identities shift and the participants seldom keep one another informed. Policemen sweep the floor and dress the baby, and mothers put men's vests over negligees while making vague appointments on the telephone. If asked, a boy will likely say he is the father, but if he were to say mother, it would cause little concern. It can be a peaceful place, the three-year-olds' doll corner, even if monsters and superheroes enter, for the cooking and dressing and telephoning are usually private affairs.

By the age of four, the players are more inclined to tell one another who they are and what they are doing. They want to coordinate themes, but it is not always possible because the boys are beginning to rebel. The girls prefer one mother, one father, and one baby per household and will play auxiliary parts when necessary: sisters, pets, grandmothers, teen-agers, and baby sitters. They would like the boys to be plumbers, carpenters, and firemen, but some boys would rather be monsters or superheroes.

The four-year-old boy is less comfortable in the doll corner than he was the year before; he may occasionally dress up in women's clothes or agree to be daddy, but the superhero clique has formed and the doll corner is becoming a women's room. For their part, four-year-old girls may intermittently exchange domestic roles for Wonderwoman and Supergirl, but the mother and baby roles reign supreme and will continue to do so throughout the kindergarten year.

The atmosphere in the doll corner changes dramatically among five- and six-year-olds. "They are bored," say some adults. "They've had enough doll-corner play." The doll corner, in fact, is entering its final phase, in which girls and boys try to end lingering confusion about the roles they play, roles they will now examine in a predominantly social context.

Although the girls officiate in the doll corner, the presence or absence of boys determines the character of the play. The more cohesive the boys' group, the mor disruptive is its doll corner play; paradoxically, "good" behavior is most often foun among the least mature boys. As th superhero dominates boys' fantasy pla the girls turn to dramatic plots that elim nate boys and bring in more sisters an princesses.

Boys set the tone and girls follow on pa allel paths. Both seek a new social defin tion for "boy" and "girl." They search e erywhere for clues, hoping to creat separate and final images. Society su plies Barbie dolls and *Star Wars*, but th children invent equally interesting syn bols by themselves.

In the class described, for example, yo hop to get your milk if you are a boy an skip to the paper shelf if you are a gir Boys clap out the rhythm of certain song girls sing louder. Boys draw furniture i side four-story houses; girls put flowers i the doorways of cottages. Boys get tired drawing pictures and begin to poke an shove; girls continue to draw. But the in age they are quickest to promote and d fend is separation by fantasy.

The four girls in the doll corner have a nounced who they are: Mother, Siste Baby, Maid. To begin with, then, the will be cooking and eating, crying an cleaning. Charlotte is the mother becaus she tells the others, she is wearing the si ver shoes. Leadership often goes to th child who is most confident about th meaning of symbols.

Teddy watches the scene as he fills u the number board for the second tim Charlotte returns his stare and says, "Yo can be the father." He inserts the last tw tiles and enters the doll corner.

ANYBODY CAN PUBLISH HIS WORKS. WHY DID WE?

And why did Newsweek call this collection "the most important book-publishing project in the nation's history"?

For years, other nations have published standard editions of the collected writings of their major authors–but we have not. Important works by many of our great writers have gone out of print or have been available only in expensive, hard-to-find editions. Until now.

In an unprecedented publishing event, The Library of America brings you the first national edition of the collected works of America's foremost authors in an authoritative, uniform series priced within reach of every reader.

For the first time in our history, you can own and enjoy all of Melville, all of Hawthorne, Twain, Emerson, Whitman, James, Poe, Thoreau–and the collected writings of many other notable American novelists, historians, poets, philosophers, essayists and statesmen. Each compact, elegant book contains from 1,000 to 1,600 pages and includes a number of works by the same author.

Books that will last for generations

These superbly constructed books, are printed on acid-free paper, handsomely bound in cloth, and come in attractive protective slipcases. Quality bindings assure that these books will last for generations.

Enjoy our nations's great literature at significant savings

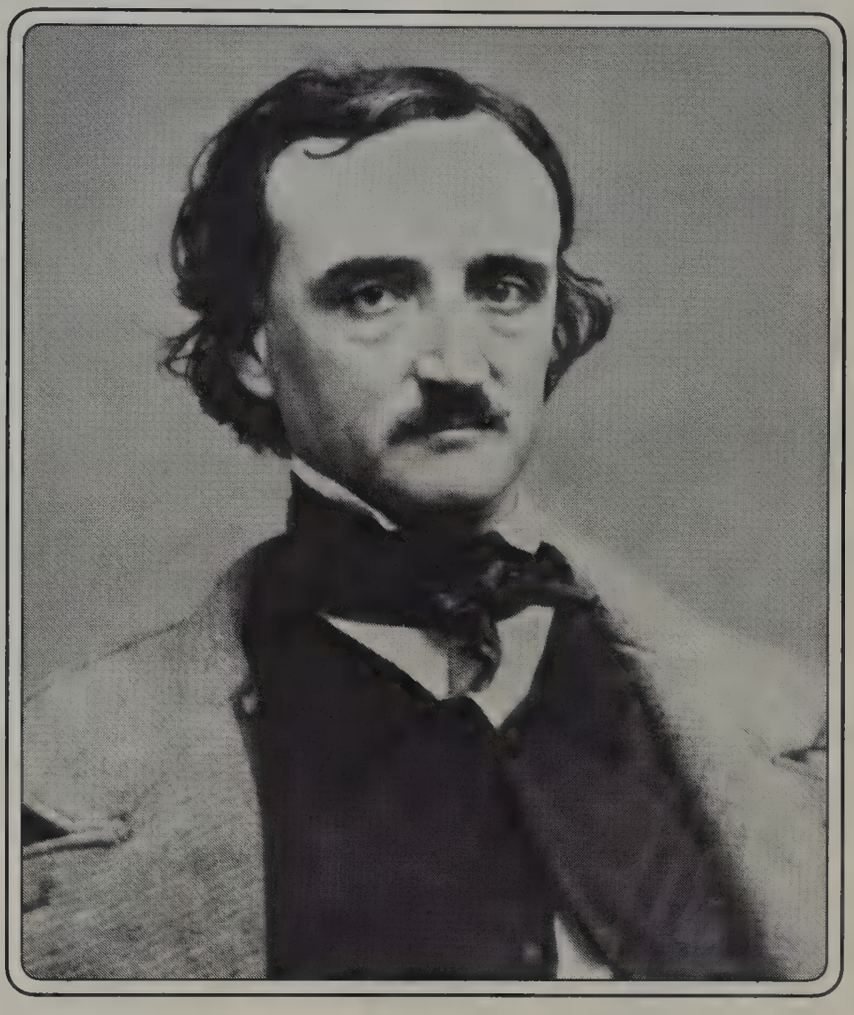
As a subscriber to The Library of America, you can begin your own personal collection of works by America's most important authors–volume by volume, direct from the publisher, at savings of up to 27% off the retail price.

Get the first volume for 15 days–*free*

Examine your first book for 15 days. If it meets your expectations–in both editorial content and craftsmanship–keep it and pay only $21.95 plus shipping and handling. Thereafter, you will receive additional volumes, one approximately every other month for your examination.

Begin your collection with Edgar Allan Poe's Poetry and Tales

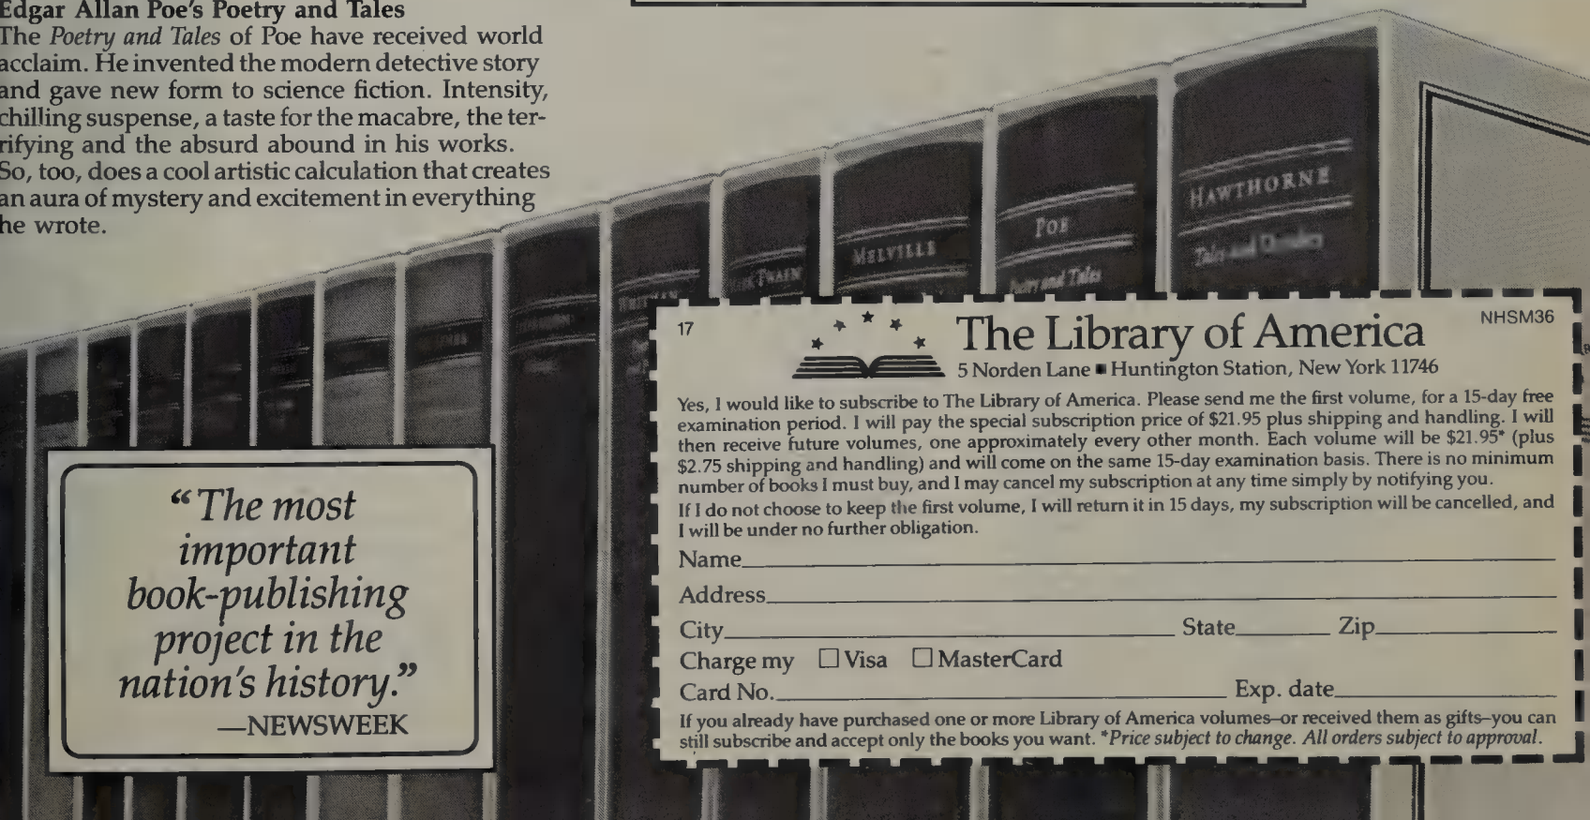
The *Poetry and Tales* of Poe have received world acclaim. He invented the modern detective story and gave new form to science fiction. Intensity, chilling suspense, a taste for the macabre, the terrifying and the absurd abound in his works. So, too, does a cool artistic calculation that creates an aura of mystery and excitement in everything he wrote.



THE LIBRARY OF AMERICA

The collected works of America's foremost authors in uniform hardcover editions

A nonprofit publishing program supported by the National Endowment for the Humanities and the Ford Foundation.



"The most important book-publishing project in the nation's history."

The Library of America

5 Norden Lane ■ Huntington Station, New York 11746

Yes, I would like to subscribe to The Library of America. Please send me the first volume, for a 15-day free examination period. I will pay the special subscription price of $21.95 plus shipping and handling. I will then receive future volumes, one approximately every other month. Each volume will be $21.95* (plus $2.75 shipping and handling) and will come on the same 15-day examination basis. There is no minimum number of books I must buy, and I may cancel my subscription at any time simply by notifying you.

If I do not choose to keep the first volume, I will return it in 15 days, my subscription will be cancelled, and I will be under no further obligation.

"Are you the father?" Charlotte asks.

"Yes."

"Put on the red tie." She doesn't know Teddy's name yet, but she can tell him what to wear because she is mother.

The girls look pleased. "I'll get it for you, honey," Janie says in a falsetto voice. She is the maid. "Now, don't that baby look pretty? This is your daddy, baby." Teddy begins to set the table, matching cups and saucers as deliberately as he did the tiles on the number board.

Abruptly the mood changes. Andrew, Jonathan, Jeremy, and Paul rush in, fingers shooting. "We're robbers. Do you got any gold?"

"No," Charlotte says, stirring an empty pot.

Jeremy climbs on the refrigerator and knocks over several cartons of plastic food. "Put up your hands. You're going to jail!"

"We're telling!" The girls stomp out in search of me or my assistant, Mrs. Brandt.

Cops and robbers is off to an early start. The first week of kindergarten is usually uneventful as children cautiously decide what they can expect from one another and from the teacher. They want to know with whom they will play and how free is free play. The four robbers in the doll corner are already a team, having practiced being bad guys in nursery school.

Every year, the girls begin with stories of good little families, while the boys bring us a litany of superheroes and bad guys. This kind of storytelling is an adjunct of play; it follows existing play and introduces new ideas for the future. Language development and creative dramatics may be on my mind, but the children take over the story-plays for a more urgent matter: to inform one another of the preferred images for boys and girls.

Teddy tells his first story at the end of the week. The boys' response is immediate and strong.

"Once upon a time there was this little boy and his name was Pretty. They called him Pretty because he was so pretty. His name was really Hansel. There was this sister. He didn't know he had a sister. The mother and father told him and then they had candy and then they went for a walk."

Andrew, Jonathan, and Paul explode with laughter. "He calls him Pretty!" "Ugh!" "Pre-e-tty!"

"He can call him that if he wants," Charlotte says.

"No he can't!" shouts Andrew. "Not if he's a boy he can't."

Teddy is not insulted, only curious. He smiles at the boys, who continue to make faces. Teddy's use of "pretty" crosses over into female territory, a subject he will learn about from boys, who care mor about boundary lines than do the girls.

"Anyway, his name is Hansel. Just ca him that." Teddy looks at the boys as h speaks.

"Are you sure, Teddy?" I ask.

"Yeah. I'm sure."

The room is quiet. Noise comes in hill and valleys in the kindergarten. Even *Star Wars* drama will eventually win down, the players scattering into gentle pursuits. Calmness follows excitement i natural rhythms, the mood shifting bac into restless gear as increased physical ten sions generate new fantasies.

Andrew runs into the empty doll corne and begins dumping clothes from shelve and hangers on the floor while Frankli watches.

"Y'all playin' house?" Franklin asks.

Andrew looks around quickly, self consciously borrowing Franklin's patois "This gonna be a spaceship. Y'wann play?"

There are six boys in the doll corner. I is the first time they have been there with out girls. Gregory and Ned totter an clump about in high heels, their arm stuck awkwardly into unfastened dresses They giggle and screech and stumble int

Uniformly exercises more muscles than any other form of exercise.

Cushioned pelvic pad keeps user from moving forward on exerciser.
Patented flywheel action provides fluid smoothness and continuity from stride to stride. Motion and resistance are the same as real skiing.
Independent arm and leg resistance settings are separate and variable.
Speedometer/ Odometer.
Built to last! Solid red oak frame.
Quiet motorless action.

Cross Country Skiing Exerciser
Better Than Exercise Bikes & Rowing Machines

The enjoyable sport of cross country skiing is cited by leading physiologists as the most perfect form of aerobic exercise. Its rhythmic total body motion uniformly exercises more muscles than other forms of exercise and its smoothness causes no joint pain or damage. NordicTrack lets you get the same top fitness building benefits year around in the convenience of your home. NordicTrack eliminates barriers of time, weather, chance of injury, etc. Very effective for weight control.

More Effective and Safer Than Rowing Machines

When rowing, the leg resistance is only as strong as the pull of the arms. Since your legs are 3 times as strong as your arms either the arms are over-worked or the legs loaf. In contrast, NordicTrack's resistance is proportioned according to the individual muscle strength – thus NordicTrack provides a far more effective workout because no major muscles are over stressed or under worked.

NordicTrack is much safer because no high back strain loads are imposed.

Much Better Than Exercise Bikes

More complete. Adds important upper body exercise and provides more uniform leg muscle usage. Higher pulse rates, necessary for building fitness, seem easier because more muscles share the exercise. Safer. Deeply bent knee motion of exercise bikes can cause knee problems. NordicTrack's erect position causes no high joint stress.

Exclusive Patented Flywheel Action Provides unmatched smoothness and continuity from stride to stride. Motion and resistances are same as in real skiing.

- Fits in your home or office
- Folds and stands on end to require only 15" x 17" storage area

Two year warranty, 30 day trial period. Call TOLL FREE or Write for Free Brochure.

NordicTrack

The Jarless Total Body Exerciser.

ne other boys, who laugh and pull them own.

Andrew darts questioning glances my way as he surveys the mess: naked dolls ace down under the crib, chairs over-urned, hats and shoes heaped on piles of resses and dishes. There is a moment of tillness, and then Jeremy drags the oven o the middle of the floor.

"This is the computer terminal," he de-lares.

"Put it over here," says Paul. He picks p the fallen chairs and sets them in two traight rows. The oven is now covered by ne shoe rack. Andrew turns two shoes ack and forth and speaks into a silver lipper: "Pilot to crew, pilot to crew, ready or landing. Snow Planet down below."

"Watch out! It exploded!"

"Darth Vader is coming!"

"*Millennium Falcon*, where are you?"

"E-ek! B-e-e-p! Erk! Erk!"

"Get the light sabers!"

Andrew runs to the wood bench. He rabs two long sticks and slams them on ne painting table. "Quick! Emergency! Where's the red paint?"

Mary Ann looks doubtful but hands im her paintbrush.

"Thanks, miss, I won't forget this." He aints a red tip on each stick and rushes ack to the doll corner. "Am I too late?"

"Just in time. Darth Vader found us, ut we got away. Wait, he might be invis-ble." Paul kicks a pile of clothes.

All the while, Franklin has been turning n unseen steering wheel, making a siren ound, and staring through squinty eyes. M-m-m . . . M-m-m . . . Darth Vader, he scapin'! Follow me, men. Ah knows his lan. M-m-m . . . K-k-k . . . P-p-ah-ah! Ah lowed his ship to pieces. He back on the Death Star."

The boys gaze at Franklin in admira-on. Ned repeats Franklin's words softly, o himself: "He back on the Death Star."

The girls don't care what goes on in the oll corner when they are not there. It is ot a place so much as an idea ready to be dapted. Right now the girls are in the lock area building a zoo. They have amed the four rubber lions Mother, Fa-ner, Sister, and Baby and put them in a wo-story house. Girls tame lions by utting them into houses. Boys conquer ouses by sending them into space.

"I wonder, why do you suppose boys ever tell stories about princes and prin-esses?" I ask one day.

"They like rougher games than girls," anie says.

"Couldn't it be a rough prince?"

The girls look surprised. "Princes are ever rough," they answer in unison.

Mary Ann is painting a row of red tu-

Nahmakanta Lake Wilderness Log Cabins

Here is one of the last few remaining wilderness areas left in Maine. We are the only camp on 4 mile long Nahmakanta Lake, only 12 miles from Mt. Katahdin. From your log cabin's screened in porch one often hears the wild cry of a loon, the splashing of a moose or deer, or a salmon rising for a fly. These and other animals plus a vast variety of unusual birds are often seen around our lake. Many woodland trails lead to remote ponds where there are canoes for either exploring or fishing for native brook trout or salmon. An ideal spot for vacations, bird watching, or just relaxing. Nahmakanta has long been noted as one of Maine's most beautiful lakes. We live close to nature and serve fresh vegetables from our beautiful garden to our guests. There are no roads, traffic, TV's or telephones. No doors need ever be locked. Over 100 years in operation. Guests are flown to camp in about 12 minutes from Millinocket Lake by sea plane.

For brochure write:

lips. "Boys don't like to be fancy. Not kings or queens."

Charlotte nods. "Princes are good guys. The boys like bad guys."

"Here's what I think," Charlotte then states definitively. "They don't want to be fancy because girls do. They just like to be not the same as us."

The boys cannot resist a giant anymore than Jack the giant killer can. At our Chinese New Year parade they conquer a fourteen-foot dragon, one of a pair outlined the day before by Franklin. The children want an even larger dragon, long enough for the whole class to carry, but I veto the idea.

"It will be too hard to stay in a single line," I insist. "Two smaller dragons are better."

The morning of the parade, Andrew and Jeremy arrive early and begin to color in one of the dragons. Then Charlotte walks in, glances briefly at what the boys are doing, and runs to the second dragon. Not told which dragon to color, the boys straddle the first dragon while the girls head for its mate. Thirty minutes later, we have a male and a female dragon, one ablaze with *Star Wars* symbols and the other with a dainty flower garden.

The boys take on their dragon's coloration. Red flashes and exploding rockets follow dotted lines until the dragon seems to breathe fire from every jagged point. It shifts and humps along the floor as the boys collide and enter one another's territory, sounding warning cries. Mrs. Brandt and I scurry back and forth, uttering words of caution and applying masking tape to twelve boys and an embattled dragon.

A few feet away, the girls murmur over their brightly petaled flowers. "This is where the godmother stays," Charlotte says, putting Cinderella under a rainbow halo. Soon there are six more Cinderellas surrounded by rainbows and tulips. "Can we paste on tissue flowers?" "Can I use the doilies?" "I'm making valentines."

The boys observe the lady dragon with considerable interest, then plunge back into battle. "Pretend this dragon sees another dragon—"

"Your dragon is done, boys," I say quickly. "I'll put it away until the parade."

Once the dragon is out of sight, the boys go off to other activities, but their play reveals that the dragon has stirred up more excitement than can be channeled into drawings. Mrs. Brandt and I have an attack of second-guessing: We shouldn't have made two dragons; the drago should have been painted red all over; should have organized boy-girl tean Any of these choices might have produc a calmer dragon. Or perhaps not.

In any case, the parade lies ahead. hopes of rehabilitating the dragon, I re a story brought to school by Karen, who Chinese. It is about well-behaved Chine children and smiling, gentle dragons.

"Here's a good idea," I say. "Let's ha each dragon carried by boys and girls gether. Just like this picture in the book

The children stare at me in astonis ment. They have purposely made a b and a girl dragon. Would a boy wear Cinderella costume on Halloween or a g dress up as Darth Vader?

"Okay. I see you don't care for the ide Then I must insist that everyone wa very, very slowly. No bumping or touc ing. No roaring."

The parade route is the long corrid between our room and another kinderga ten class. Our plan seems simple. The bo and girls are to walk in adjacent rov holding the two dragons as if they are o posite sides of one animal: boys on t right; girls on the left. In theory, t dragon will move quietly down the ha way; however, before we reach the first tersection, the boys' dragon rips apart

China is a must in your travels. And it's a must to travel there like Royalty on Royal Viking Line. No one else shows you every important place—at just the right unhurried pace. With every comfort and convenience. A spaciousness approximating grandeur!

Our 13-day fall cruises between Hong Kong and Japan depart this September and October. With a free three-day land package in Hong Kong, two complimentary nights at one of Beijing's modern, new hotels, and all shore excursions included.

If the readers of *Travel/Holiday* voted us #1 in the world, you know we must be #1 to China. We're certainly the most experienced. Come see for yourself!

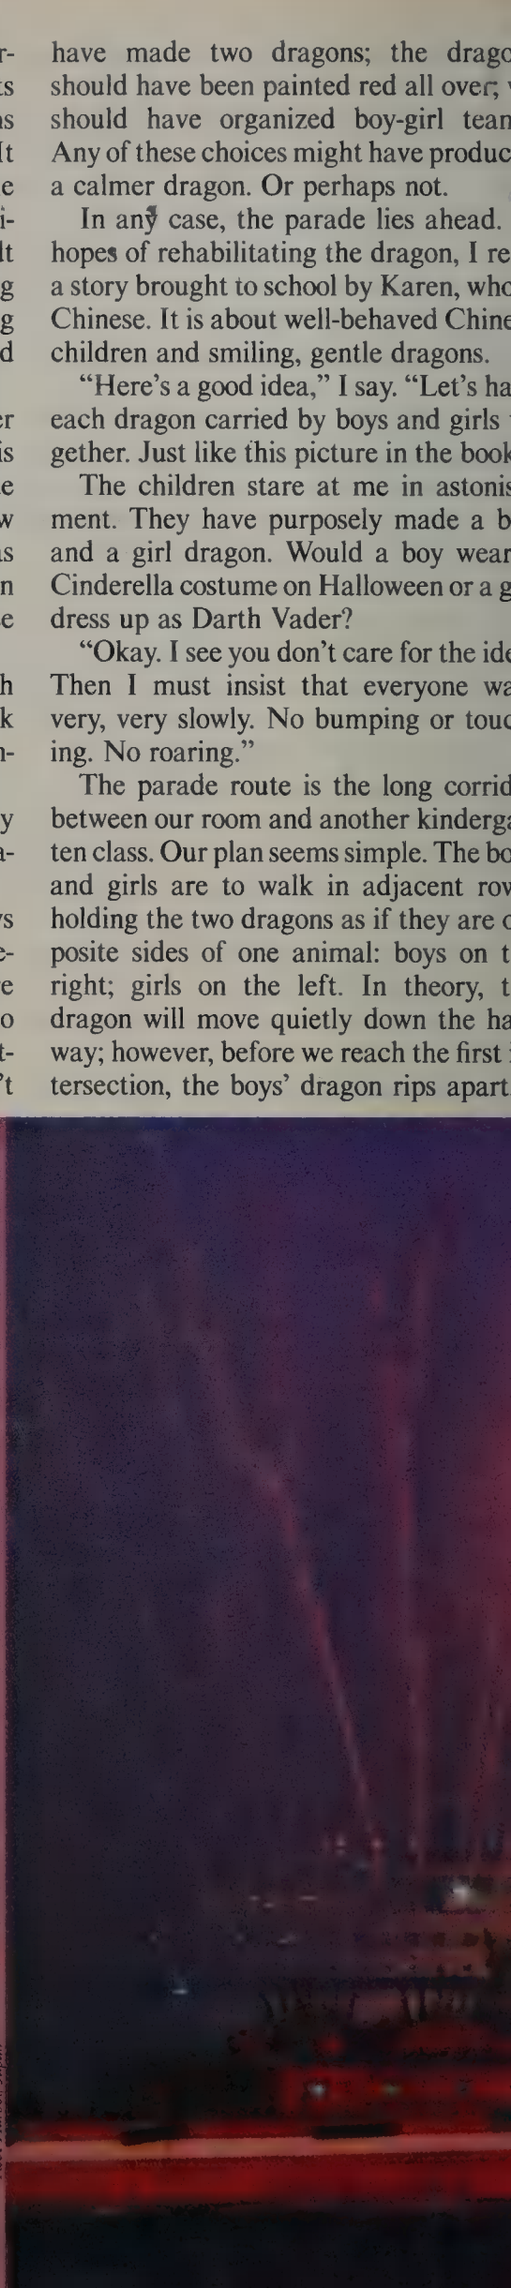
World Wide cruising. World Class style.



Kobe Harbor, Japan

nd Jonathan back for the mending tape, nd by the time he returns, the dragon has en torn twice more. The girls' side arely flutters as the disfigured dragon rches and groans on its right side.

Mrs. Brandt and I perform quick sur- ery on the dragon, whispering directions. Come on, boys, people are watching. Valk calmly. Stop growling. Breathe eeply."

The more I glare at the boys, the less co- rdinated they become. Heads, arms, and gs are thrust in all directions, jerking and ucking into the dragon, which continues tear. People along the route cannot help ughing as the boys increase their manic ehavior.

Mrs. Brandt and I hurriedly confer. We ave two choices: send the boys back in isgrace or ignore them. One look at them, owever, shows they do not realize they re in disgrace, so we decide to act as if othing unusual is going on.

The march through the other kinder- arten room is brief. "Your dragon is orn," a girl tells us. "On one side," I reply. Ve rush through a Chinese song that re- eats "Good Luck, Happy New Year" hree times and we return to our class. The oys race through the hall waving pieces f the dragon, but Mrs. Brandt and I walk long slowly with the girls, saying nothing.

In the room, the boys have already started to build with blocks. The dragon lies in a heap on the table.

"What did you think of the parade, boys?" I ask.

"Great!"

"Wonderful!"

"We had a great dragon!"

The boys mutilated their dragon and disrupted the parade, yet seem unaware that anything is wrong.

I turn to the girls: "How did you like the parade?"

"Wonderful!"

No one mentions the boys' behavior. Either the girls didn't notice the chaos or else they expect boy dragons to be wild.

"You said we could tape our dragon to the wall," Charlotte says.

"You can. But what about the boys' dragon?"

I put both dragons in the middle of the circle and call everyone to sit down.

TEACHER: The girls want to hang up their dragon.

ANDREW: Ours too.

TEACHER: That's what I want to talk about. Yours is torn.

PAUL: Who did it?

TEACHER: You boys did it.

JONATHAN: It only got torn two times. 'Member when I got the tape?

TEACHER: But no one else touched your dragon. Only you boys.

JEREMY: The other side didn't get torn.

TEACHER: The other side walked slowly.

FRANKLIN: We was too walkin' slow.

ANDREW: Someone came and tore it up.

TEACHER: Who? When?

CHARLOTTE: Maybe some kid that doesn't like dragons.

MARY ANN: Some kid that fights with them in the playground.

I decide not to lecture on the events of the parade. The girls remained calm because their fantasies placed them in an enchanted garden, for which they received compliments plus the added bonus of an undamaged dragon. The boys took the dragon as seriously as Jack would have. They confronted it, tricked it, and destroyed it. It is the teacher who does not take dragons seriously, who prefers and expects dragons—and heroes—to remain inside the fairy tale book.

Yes. Royal Viking.

A Nest of Dinosaurs

Early in the year 1920, a young mammalogist with the American Museum of Natural History, Roy Chapman Andrews, invited the Museum's president, Henry Fairfield Osborn, to lunch. After lunch, as reported by Andrews in his autobiography, Osborn leaned back in his chair, lit his pipe, and asked, "Well, Roy, what is on your mind?"

Andrews began to talk about his plan for a new expedition, one that he had been turning over in his mind for eight years. When Andrews had finished, Osborn began asking questions. Finally, he said, "Roy, we've got to do it."

Andrews's grand plan was based on an earlier prediction by Osborn that central Asia would turn out to be the birthplace and dispersal point of the terrestrial life of Asia, Europe, and America—and that the area would yield the fossils of the earliest hominids, the so-called missing link. Andrews wanted to test Osborn's theory with an ambitious expedition. "We should try," he told Osborn, "to reconstruct the whole past history of the central Asian plateau. We ought to learn about its geological structure, fossil life, its past climate and vegetation. We should make collections of its living mammals, birds, fish and reptiles. We should map the unexplored and little-known Gobi Desert."

To do this, Andrews proposed to lead an array of experts—from cartographers to paleontologists—to the heart of Outer Mongolia. As transportation, Andrews proposed a fleet of motorcars, which he felt could cross the level, gravelly sands of Mongolia. A caravan of 125 camels, loaded with gasoline and provisions, would resupply the expedition every 600 or 700 miles. The expedition's dozens of scientists and assistants would spend a minimum of five years in the field, using Peking as a base during the winter months.

It was a bold plan. Nothing remotely like it had ever been attempted. Mongolia—a huge and nearly uninhabited area of more than one million square miles—was split into two regions, the gentle hills and fertile plains of Inner Mongolia, controlled by China, and the parched wasteland of Outer Mongolia, with the Gobi Desert stretching across its entire centra portion. Politically, the area was unstable Russia was just recovering from its revolu tion, and China was in the throes of a lon series of civil wars. Mongolia, which on year later (1921) would undergo its ow revolution, existed in a state of virtual an archy, overrun by rifle-toting brigands.

The proposed expedition would als face some of the most extreme weathe

Investors:

Right now, when your taxes are due, you realize it's not what you earn, but what you keep that counts. And with Nuveen you earn a lot and you keep a lot.

As an intelligent investor, chances are you put your money in CDs, money market funds or the market last year. And you did well.

But now you're paying for it. In taxes. Chances are, you're about to write a check to pay the tax on the money you earned.

A check which can slash your earnings as much as 50%, depending on your tax bracket.

At Nuveen, we'd like to suggest you invest in something where you don't have to pay federal income taxes on what you earn.

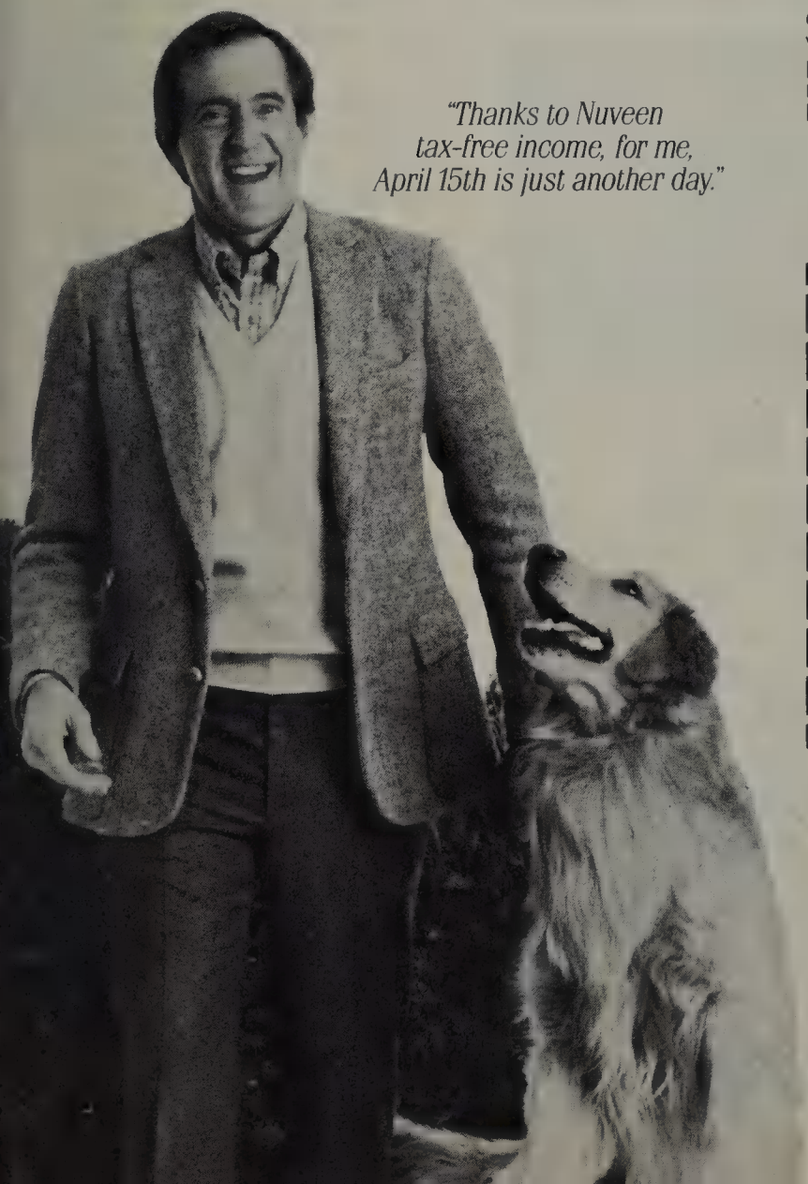
The current Nuveen Bond Fund will pay you interest at the tax-free rate of 9.70% to 9.94%*

And you don't pay a penny in federal tax on it. What you earn you keep.*

Which can make Nuveen, a prudent investment, worth a lot more to you.

And isn't that what we all want; to keep a lot more of what we make.

For more complete information on the Nuveen Tax-Exempt Bond Fund, Series 314, including charges and expenses, send for a prospectus by telephoning or mailing the coupon. Read it carefully before you invest or send money.



"Thanks to Nuveen tax-free income, for me, April 15th is just another day."

*This return represents the net annual interest income, after annual expenses, divided by the public offering price on 1/11/85. The return will vary with changes in interest income or the public offering price with the payment option chosen and with the amount invested. Interest income will remain the same as long as the portfolio remains intact. Interest income may be subject to state and local taxes. Member SIPC.

The expedition cars with cavalry escort

conditions on the planet. Winter temper tures in Outer Mongolia plummet to 40 50 degrees below zero. Sudden win storms sweep down from the Arctic ar the Siberian steppes and scour the lan scape, and snow usually doesn't melt unt June. Then, in July and August, daytim temperatures soar to 110 degrees in th shade, while nights remain cold.

Physical dangers aside, the greatest ris was that the expedition would fail. Onl one fossil—a rhinoceros tooth—had eve been found in central Asia. Osborn's the ory was based partly on finds in Europ India, and eastern Siberia—forming "ring" around central Asia. Because this, he speculated that early land life ha evolved in Central Asia itself.

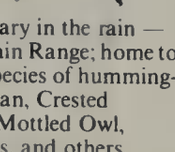
Osborn enthusiastically endorsed An drews's plan. Here was a chance to asso ciate the Museum (and himself) with possibly unprecedented scientific disco ery, something that would live forever i the annals of science.

When the Museum announced plan for the expedition, newspapers across th country published the story on their fron pages. What especially caught popular at tention was the mention of a search for th missing link. During the following weeks thousands of telegrams and letters poure into Andrews's office at the Museum most from people seeking a job with th expedition. Offers of assistance cam from every imaginable quarter, includin letters from clairvoyants and young boy looking for adventure.

Shortly before Andrews departed fo Peking in March 1921, to set up his bas and prepare for the first leg of the journey he had one last meeting with Osborn. Th younger man expressed his fears that th expedition would be his "swan song" in ex ploration. "Nonsense, Roy," Osborn re plied. "The fossils are there, I know they are. Go and find them."

Trinidad & Tobago

The Asa Wright Nature Centre And Lodge



A 200-acre wildlife sanctuary in the rain — forested Northern Mountain Range; home to a colony of Oilbirds, 12 species of hummingbirds, channel-billed Toucan, Crested Oropendola, Antshrikes, Mottled Owl, trogans, tanagers, bellbirds, and others.

Trinidad's species include an impressive 400 birds, 108 mammals, 55 reptiles, 25 amphibians and over 617 butterflies.

Individual and group tours to the Centre, Trinidad, and its sister island of Tobago are conducted throughout the year.

Special tours include our summer workshops in Ornithology, Botany, Tropical Ecology, Entomology and Nature Photography and Art; and the Annual Audubon Christmas Bird Count.

AMNH

In April 1922, Andrews and his motorade drove through the gateway of the reat Wall of China and headed out over ıe grasslands of Inner Mongolia. For ıree days the cars slid along a muddy ack, stopping along the way to allow Anrews to explore various outcrops.

On the fourth day, Andrews arrived at ıeir rendezvous point early and set up ımp. In the final expedition report, *The lew Conquest of Central Asia*, he decribed the events that followed. As he rexed in front of his tent, the last two cars the caravan drove rapidly into camp. he men were obviously excited. The exedition paleontologist, Walter Granger, imbed out of the lead car, puffing viontly on his pipe. "Silently," Andrews rote, "he dug into his pockets and proıced a handful of bone fragments; out of is shirt came a rhinoceros tooth, and the arious folds of his upper garments ielded other fossils." Granger laid them ut before Andrews and held out his hand. Well, Roy," he said, "we've done it. The uff is here."

The stuff really was there. As they lunged deeper into Mongolia, they found ıore and more fossil evidence of dinoaurs and early mammals. In the flat esert, most outcrops could be seen miles way, and often all they had to do to disover new fossils was to drive from one utcrop to another.

The expedition continued to unearth ıajor fossils, and Osborn was pleased. Alhough they had not yet located the missg link, they had uncovered traces of anent human camps—some 20,000 years ld—of an unknown people they called ıe Dune Dwellers. Andrews hypothezed that the Dune Dwellers were the abriginal descendants of the earliest umans; he hinted to Osborn that the issing link would turn up at any time.

But on July 13, 1923, the expedition

made a discovery that made everyone forget about the missing missing link. George Olson, a young assistant in paleontology, reported at tea that he had come across some fossil eggs weathering out of the sandstone at the Flaming Cliffs of Shabarakh Usu. Andrews assumed the eggs to be natural sandstone concretions, which could be found almost everywhere. Nevertheless, after tea, Olson led them to his find, where three unmistakable, if broken, eggs lay next to a sandstone ledge, with more bits of shell sticking out of the rock. Could these be dinosaur eggs? No dinosaur eggs had ever been found, and scientists didn't know how dinosaurs bore their young. (While many extant reptiles do lay eggs, some bear live young.) They criticized the conjecture from every viewpoint but finally concluded that the eggs were dinosaurian.

With mounting excitement, they began to brush away the sand from the ledge, exposing more of the remarkably well-preserved fossil eggs. The usual bumps, rugosities, and pores were clearly visible. Solid evidence that these were dinosaurian emerged shortly. Lying on top of the eggs was the fragmentary skeleton of a tiny, toothless dinosaur that, Andrews hypothesized, had been eating the eggs when both beast and nest were covered by sand. More eggs appeared to be encased in the sandstone, and Granger carefully cut a large block of it out of the ledge and shipped it intact to the Museum. Back in New York, paleontologists painstakingly chipped away the remaining rock, revealing a baker's dozen of large, oblong eggs arranged in two concentric circles, just as the dinosaur had laid them millions of years ago.

The expedition dug up dinosaur eggs from a number of species, a very few of which contained fossilized skeletal material. While this discovery brought fresh enthusiasm (and funds), it also brought problems from an unexpected quarter. When Andrews returned to the States the following winter to raise more money for the expedition, he was amazed at popular interest in the eggs. As a fund-raising stunt, he decided to "auction off" an egg. After spirited bidding, Col. Austin Colgate won out with a $5,000 bid (he gave the egg to Colgate University). But when the Chinese and Mongolians heard about the auction, they assumed that their native treasures were enriching the expedition members. This misunderstanding was one of many factors that led to the cancellation of the expedition years later. (The expedition also uncovered tiny mammalian remains in the same strata, which led to the theory that these mammals were

egg eaters and may have been an important factor in the extinction of the dinosaurs—a theory still debated today.)

The dinosaur eggs were only one of many important discoveries made in Mongolia; others were the well-preserved remains of many early mammals and dinosaurs and archeological finds. Although the explorers never found the missing link, they did shed substantial light on the evolution and dispersal of mammals in Asia and filled in gaps in our knowledge of dinosaur diversity.

China's worsening political situation and rising hostility to Westerners forced the cancellation of the 1926 and 1927 expeditions. But Andrews had made up his mind that whatever happened, he was going to make one last try to get into Mongolia in 1928. By spring of 1928, however, conditions on the Mongolian plateau had become very bad. Bandits swarmed over the area in such numbers that everyone who could be robbed had been, and the bandits themselves were starving. Finally, the Chinese government made a truce with the bandits, allowing them to extract specific amounts of "protection money" from traders—$5 per camel and $100 per car. Andrews could only get as far as Inner Mongolia, where he explored a remote area in the northeast. At the end of that year, a group called the Society for the Preservation of Cultural Objects accused the expedition of having "stolen China's priceless treasures" (among them the dinosaur eggs) and denounced its members as "spies against the government" who had been "searching for oil and minerals and smuggling opium." The Chinese authorities at Kalgan seized the expedition's collections, and Andrews spent six weeks negotiating with them to get his crates of fossils back.

In 1929, the Society's onerous demands before it would allow Andrews to undertake a new expedition caused him to abandon his plans for that year. In 1930, Andrews was able to make arrangements with the Society for another trip, and once again he set out to explore Mongolia. This time the expedition made outstanding fossil discoveries, especially of large mammals; among these was an entire graveyard of rare, shovel-tusked mastodon skeletons, previously known only from a few bones. On this trip they had their closest call with bandits, who attacked a lone expedition member. The man drove them off after shooting one in the ear and killing another's horse.

The 1930 expedition was Andrews's last; scientific work in Mongolia had become too difficult and too dangerous. But his influence is evident throughout the

SEE THE WORLD THROUGH AN EDUCATED EYE.

To see the world is one thing, but appreciating its treasures is something else.

That something else is a Swan Hellenic Art Treasure Tour. Each unique tour is accompanied by a guest lecturer, an expert whose informative talks will bring a deeper awareness and appreciation of the art, architecture, history and natural beauty you will encounter on your tour.

And what tours to choose from. Swan Hellenic Art Treasure Tours cover the world. From Britain's heritage to Europe's history beauty of Latin America. From the Middle East to Australia. Even the rich treasures of India and the Orient. With over 140 departures to choose from, we're sure you'll find at least one that will particularly delight you.

Museum today. Every fossil hall is packed with his finds, and thousands more—still studied diligently by scientists from around the world—remain in drawers and on shelves in the Vertebrate Paleontolog

At the American Muse

Musical Tantric Rituals

The harmonic chords and metaphysical texts of Tantric Buddhist rituals were once known only to Tibetan monks. Now Museum members and friends can be the first in this country to hear the Gyuto Tantric Monks, students of the Dalai Lama, in their American première, Wednesday, March 20, at 7:30 P.M. in the Auditorium. A second show will be offered on Thursday, March 21, at 7:30 P.M. in the Hall of Ocean Life.

Since the Chinese invasion of Tibet in 1950, thousands of Tibetans have been living in exile. Among them are the Gyuto monks, who, having left their homeland, feel they can now share certain of their rituals with the uninitiated. The monks' chants generally involve one resonant low note around which others are woven. Many of the notes they sing are well below the bass limit of Western singers, and several monks are capable of singing three-note chords. Some chants are accompanied by sacred instruments.

The program will be narrated by Robert Thurman, a leading American authority on Buddhism. Tickets for the performances are $7.50 for members and students and $12.50 for nonmembers. For information, call (212) 873-1327.

Captured Motion

The grace and precision of animals in motion were remarkably captured by S. Harmsted Chubb in skeletal specimens mounted at the Museum from 1903 to 1949. Many of Chubb's major works will be featured in a new exhibition, *Capture Motion: Skeletal Studies of S. Harmsted Chubb*, which opens in Gallery 1 on Tuesday, March 19. Designed by Ralph Appelbaum Associates, the exhibition includes videos of current research on animal movement. Each of the mounts he created are "doing something," Chubb said in 1949. So with a little imagination, viewers can stand back as a wolf pursues a wild horse or a human reaches for the bridle of another horse.

Shadows of Myth

The shadow play, one of the most ancient forms of theater in existence, combines slapstick comedy with high drama and uses mythical stories from the past to bring to light the current situation of human beings. In a bilingual (English an

epartment. Visitors can find the first di-osaur eggs in a glass case in the Hall of ate Dinosaurs, resting in their nest, 2,000 miles from their original home.

Douglas J. Preston

awi) performance for all ages, the hadow Play Theater Company will resent *Wayang Kulit*, traditional Bali-ese shadow puppetry. *Wayang Kulit* will e performed on Saturday, March 9, at :00 P.M. in the Kaufmann Theater. Ad-nission is free, and further information an be obtained by calling (212) 873-300, ext. 559.

Shadows and Footprints

The sperm whale's social behavior and cology have long been mysteries, but a ew film, *Shadows and Footprints: Great Whales of Sri Lanka*, offers some clues. Narrated by Gregory Peck and with an riginal score by Paul Winter, the film fol-ows scientists at the Indian Ocean Whale Sanctuary near Sri Lanka, as they inter-ct with whales under water. After the creening, staff members of the New Eng-and Aquarium will speak about their tudies of stranded marine mammals and iscuss the significance of whale commu-ication. The program, sponsored by the American Littoral Society, will take place n Wednesday, March 13, at 7:30 P.M. in he Auditorium. Tickets are $6 for Mu-eum members and $7 for nonmembers nd are available by calling the Society at 201) 291-0055.

Latin Music for Children

The group *Alborada Latina* will offer a ampling of Latin American music, from ight-hearted folk music to works of in-riguing complexity, in a program created specially for children. The group's reper-oire includes classical and traditional nusic by Latin American composers such s Heitor Villa-Lobos and Simon Diaz nd classical favorites by Bach, Rossini, nd Poulenc. The free performance will e offered twice, at 2:00 and 4:00 P.M., on Sunday, March 17, in the Kaufmann The-ter. For more information, call (212) 873-1300, ext. 514.

Planetarium Events

Laser visuals combine with rock music o create a dazzling experience of sight nd sound in the world première of *Heavy Laser* at the Hayden Planetarium. The new show features the music of the Police, Van Halen, the Who, and Rush. Showings are at 7:30, 9:00, and 10:30 P.M., and ad-mission is $5.00. For additional informa-ion, call (212) 724-8700.

600 MILES AND 4,000 YEARS INTO HISTORY.

Cruise the Nile with an educated eye.

Timeless yet ever changing, ancient yet modern, Egypt presents a paradox worthy of the Sphinx itself.

On a Swan Nile Cruise, the greatest monuments of man's existence come alive within your reach, as you explore the wonders of this legendary land.

From Cairo to Assuan you will be accompanied by a guest lecturer, an expert whose informed but informal talks will blow the dust off the centuries and put into context the places you will be visiting.

There are over 30 Nile Cruise departures from March, 1985 through June, 1986. And Swan offers a choice between all inclusive or cruise only rates.

To find out more, see your Travel Agent, or write Exprinter for a free color brochure.

And join us for a journey into the past that will surely become the experience of your lifetime.

The Great Breadfruit Scheme

l bountiful tree still bears the stigma of its past

y Gerald Oster and Selmaree Oster

Children in the Haitian village where e have a home often approach visitors om the city with the question, "Do you ke breadfruit?" This is a little game they ay to distinguish city people who are ntemptuous of rural life from those who e sympathetic. Although the breadfruit a tasty and nutritious fruit, produced by tree that grows abundantly in the soft, umid soil of tropical lowlands, many Hai-ans hold it in low esteem. Perhaps one eason for this attitude is that the bread-uit is widely used as food for pigs. An-her, more likely reason is that eigh-enth-century colonists introduced the readfruit into the Caribbean area to pro-de food for slaves. In Haiti, which be-ame the first black republic, this infa-ous history may have translated into a eling that the fruit is fit only for pigs and ountry bumpkins.

The breadfruit tree (*Artocarpus altilis*) a seedless plant; grown from root suck-s, it requires some care to propagate. It ems to have originated in the Malay Ar-hipelago, where it has been cultivated nce antiquity. From there people spread to the Polynesian islands. (According to e mythology of the Marquesas Islands, e god Pukuha traveled to the under-orld to fasten a hook to the breadfruit ee, and succeeded in gradually pulling it p.) The tree became so crucial to daily fe in the South Pacific that Polynesians ere unable to conceive of a land where e breadfruit did not exist. Traditionally, olynesians regarded the breadfruit tree ith the same reverence accorded to the ango tree in India. It yields bountiful od and provides welcome shade. It is urdy and not easily damaged by strong inds, an important consideration for a urricane-prone region.

The first detailed description of the breadfruit published in the West appeared in William Dampier's *New Voyage Round the World*, printed in 1697. Dampier was an English explorer of the South Pacific who later became a buccaneer along the Spanish Main. (He also rescued the shipwrecked Scottish sailor Alexander Selkirk, whose adventures provided the basis for Daniel Defoe's novel *Robinson Crusoe*.)

The breadfruit found its champion in the British naturalist Joseph Banks, who accompanied Capt. James Cook on the first (1768–69) of Cook's three scientific expeditions to the Pacific. Banks himself financed the expedition, which enormously expanded the West's knowledge of the flora and fauna of the South Pacific, including Australia. Banks's enterprise, employing appropriate specialists to gather information with a view to possible economic gain, is one of the earliest examples of sponsored scientific research, a commonplace today.

In the course of their travels, Cook and his men were impressed with the voluptuous life of the natives of Tahiti and attributed their good fortune largely to the breadfruit. About the trees, Captain Cook wrote in his journal,

> the Earth almost spontaneously produces [the trees] or at least they are raised with very little labour, [and] in the article of food these people may almost be said to be exempt from the curse of our forefathers [since] scarcely can it be said that they earn their bread with the sweet of their brow, [for] benevolent nature hath not only supply'd them with necessarys but with abundance of superfluities.

Joseph Banks's first impression of Tahiti was of a well-kept park, since the groves of breadfruit trees were so shady that there was no underbrush. At the end of the voyage, Banks met with King George III to discuss the botany of the South Seas, inaugurating an enduring friendship based on their mutual love of gardens. It was Banks who convinced the king that breadfruit would make a cheap food for slaves in the British West Indies.

The products of the West Indian colonies, notably sugar, coffee, cocoa, and indigo, were a principal source of revenue for eighteenth-century England. To cultivate these cash crops profitably, slave labor was needed, and a major factor in the colonial economy was the cost of feeding the slaves. Garden space had to be set aside, and slaves needed time off to plant their own food. They were allowed Saturday afternoons, as well as Sundays during off-crop season, to work their own gardens. The English efficiency experts reasoned that breadfruit would be the ideal fuel for the slave machines, or "pieces of the Indies," as the slaves were called when transported from Africa.

Banks's idea was quickly taken up by wealthy British investors, who felt that importing the breadfruit into the colonies would reap even more profits for the slave owners. (Even before any trees were delivered, Banks was being thanked for his efforts by the Jamaican House of Assembly, which consisted mainly of slave owners.) In 1789, George III commissioned Lieut. William Bligh to carry breadfruit trees from Tahiti to the British colonies in the Caribbean. A botanist was assigned to Bligh's ship to carry out Banks's precise written instructions, and under his supervision, some one thousand pots of young breadfruit trees were loaded in Tahiti. Bligh had encountered the breadfruit be-

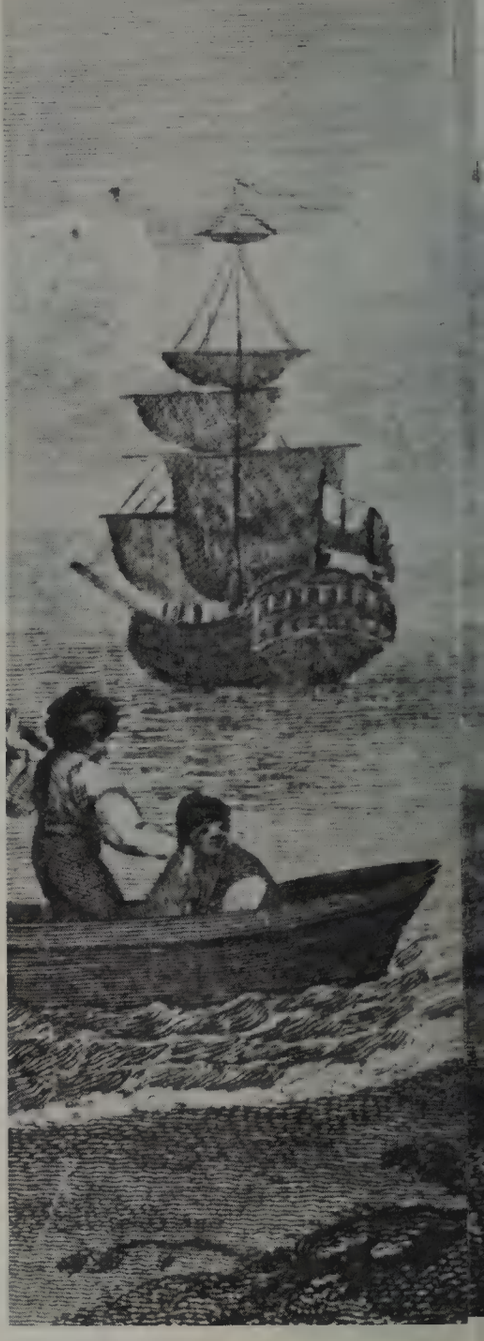
Robert Frerck; Odyssey Productions



fore, while ship's master on Captain Cook's third (and for Cook, fatal) voyage in 1776–79. Now he commanded his own ship, H.M.S. *Bounty*.

During the long sea voyage, the maintenance of the living cargo proved to be physically taxing, a chore beyond the call of the seamen's normal duties. The thousand plants in their soil-filled wooden casks with gravel drainage bases had to be transferred daily from below decks, where they were kept warm at night, to above deck for sunshine. The breadfruit, being native to the humid tropics, also required copious amounts of water to stay alive. Bligh's efforts to water all of the plants curtailed the crew's supply of drinking water. This, coupled with his overbearing manner toward the men, led to Bligh's downfall. Following the celebrated mutiny, Bligh's precious plants were thrown overboard and he was put in an open boat. After a precarious 4,000-mile trip at sea and his subsequent return to England, the indefatigable Bligh, again at the urging of Banks, returned to Tahiti for a second try. Evidently, Banks still felt that the great breadfruit scheme was vital to the British economy. This time the breadfruit plants must have been well watered because when Bligh's ship *Providence*, with its 1,200 trees, sailed into Port Royal, Jamaica, in 1793, it was described as a floating forest.

But the breadfruit investment scheme was no bonanza. The slaves did not take kindly to the new fruit, preferring the familiar plantain, or cooking banana. (The Spanish had imported the plantain tree into the West Indies in 1500, the same year they initiated the African slave trade to the Caribbean.) In any case, placed there against their will, the slaves probably would have resented any new food proffered by the colonists. (A somewhat analogous situation was the reluctance of Irish Roman Catholic tenant farmers, in 1845, to accept the British offer of maize in place of the potato. The potato crop had been decimated by a fungal disease, but Irish resistance to maize was so extreme that people chose to starve rather than grow it. Also, the Irish could emigrate; slaves did not have that option.)

In Jamaica, although Bligh's trees were propagated (and some of the originals survive in the botanical garden at Kingstown, on the island of Saint Vincent), only pigs ate breadfruit for half a century after the tree's introduction. The breadfruit became acceptable human food only after the emancipation of the slaves in 1838. In Haiti, the breadfruit's introduction is popularly credited to Henri Christophe, a former slave in the British colony of Sa[int] Kitts, who became the king of northe[rn] Haiti in the early nineteenth century. [Sl]

The breadfruit is a starchy food co[m]parable to the plantain in both carboh[y]drate and vitamin B content. But t[he] breadfruit has considerably more fib[er] than the plantain. Soured by long storag[e] the breadfruit also becomes very rich in [vi]tamin C, just like the fermented form [of] cabbage, sauerkraut. In his second vo[y]age, Captain Cook demonstrated that T[a]hitian breadfruit contributed to his men's resistance to scurvy, a disease caused b[y] lack of vitamin C in the diet and th[e] plague of sailors on long voyages. For th[is] contribution to clinical medicine, Coo[k] was awarded the prestigious Copley Medal of the Royal Society of London.

The taste of breadfruit has often bee[n] praised. One of Captain Cook's seamen, quoted in the August 29, 1771, edition of the *London Evening Post*, said tha[t] "breadfruit when baked is superior to an[y] [bread] made with wheat." Alexande[r]

is then peeled and the hot pulp
eaten. The children of our village regard the baking of breadfruit as a major event. They run through the coconut groves seeking fuel for the fire, and the meal itself is a time for the great Haitian pastime of storytelling.

If allowed to ripen, the breadfruit turns brown and the pulp becomes yellowish, mushy, and sweet. As with the banana, the ripening takes place as enzymes convert starches into sugars. Haitian families usually feed ripe breadfruit to their pigs (fallen fruit used to be scavenged by pigs as well, but because of a swine disease, Haiti's freely roaming native pigs have been replaced by penned imported breeds).

In Polynesia, however, the ripened fruit is part of the traditional cuisine. In its sweet form, it may be served uncooked as a baby food. Flavored with lemon juice it tastes vaguely like applesauce. The soft breadfruit is also used in pies and puddings. When preserved for a long period of time, the mushy breadfruit becomes vinegary and is used to spice boiled, firm breadfruit. The Tahitians' method of preserving breadfruit is described by Captain Cook in his journals:

Of bread fruit they make two or three dishes by beating it with a stone pestil till it makes a paste, mixing water or cocoa nut liquor or both with it and adding ripe plantains bananoes Sour paste &c[a], this last is made from bread fruit in the following manner. This fruit from what I can find remains in season only 8 or 9 months in the year and as it is the chief support of the inhabitants a reserve of food must be made for those months when they are without it; to do this the fruit is gather'd when upon the point of ripening, after the rinde is scraped off it is laid in heaps and cover'd close with leaves where it undergoes a fermentation and becomes soft and disagreably sweet, the core is then taken out and the rest of the fruit thrown into a hole dug for that purpose the sides and bottom of which are neatly laid with grass, the whole is cover'd with leaves and heavy stones laid upon them; here it under goes a second fermentation

and becomes sourish in which condition they say it will keep good 10 or 12 Months, as they want to use it they make it into balls which they wrap up in leaves and bake in the same manner as they do the fruit from the tree, it is then ready for eating either hot or cold and hath a sour and disagreable taste. In this last state it will keep good a Month or six Weeks, it is called by them Mahai and they seldom make a meal without some of it one way or another.

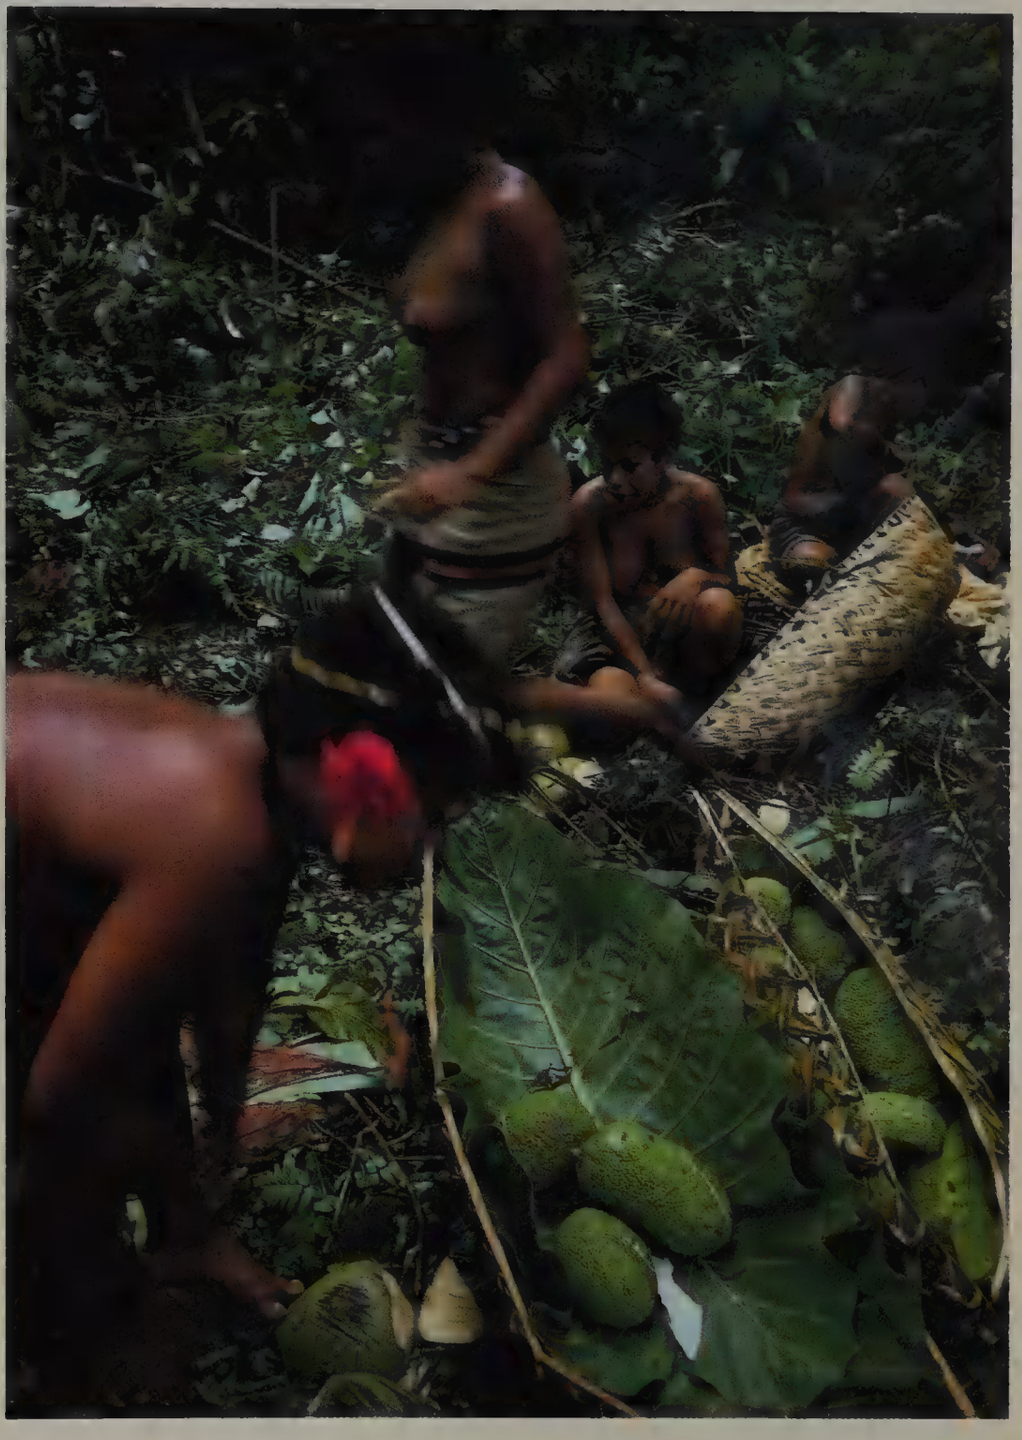
In Tahiti, where the rainy days are spread uniformly throughout the year, fruit from one tree or another is available over long periods. In the Caribbean, however, the breadfruit crop appears twice a year following the most intense rainy months, usually May and October. In season a tree will bear about 500 fruits, which dangle at the tips of the branches like decorative balls on a Christmas tree.

The breadfruit is a good source of ca bohydrates: a single fruit provides 2,70 calories, roughly the minimum daily cal ric requirement for a fieldworker. Hov ever, a diet consisting exclusively breadfruit is incomplete because it lac protein. Protein deficiency is particular acute in the tropics because of the pr dominance of such high-carbohydra foods as taro, manioc, corn, and suga

Nicholas DeVore III; Bruce Coleman, Inc.

In the Caroline Islands of Micronesia, a woman, left, pounds unripened breadfruit for incorporation into a paste. Below: Women gather a variety of breadfruit that has been picked while still green. If allowed to ripen, the starchy flesh of the fruit becomes sweet and, eventually, vinegary.

Nicholas DeVore III; Bruce Coleman, Inc.



Where sugar is plentiful and protein scarce, a mother may give sugary water to her weaning child to satisfy its hunger. Such two- to three-year-olds can develop kwashiorkor, a protein-deficiency disease characterized by sparse, reddening hair and a bloated appearance. These "sugar babies," most commonly seen in times of famine, are severely immunodeficient, easily succumbing to diseases, such as measles, that are not serious for normal children.

One cheap source of protein (and fat as well) available in the tropics is the breadnut, the seeded form of the seedless breadfruit tree. Botanists are divided as to whether the seedless form originated from the seeded form or developed as a hybrid of the seeded form and another seeded species. Despite its importance as a food plant, the breadfruit's botany and classification still have not been fully explored. (Adding to the confusion, the popular terms *breadfruit*, *breadfruit tree*, and *breadnut* also apply to a number of other species of plants.)

Breadnuts, which resemble chestnuts, may be boiled, then peeled, mashed, and sweetened to feed small children. Others eat breadnuts roasted—they taste like

Along with their fruit, breadfruit trees, right, provide shade, leaves for fodder, a latex glue, and other dividends. Opposite: The male catkin, the large leaves, and the globular fruit of the breadfruit tree.

roasted Italian chestnuts. The French brought the breadnut to Haiti and their other Caribbean colonies in 1783, ten years before the seedless breadfruit arrived in Jamaica. But for some reason, the breadnut never became as popular, even though it is easier to cultivate. For Haitians, the breadfruit remains *l'arbre véritable,* "the true tree."

The breadfruit tree provides more than food. Because it bears leaves year-round, it offers ample protection from the intense sunlight of the tropics. The fully grown tree is thirty to sixty feet high, with a spread of about half its height. The dark green leaves, which make excellent cattle fodder, are one to three feet long and of a shape and texture very much like that of the fig tree, which is in the same family. When in bloom the breadfruit tree is particularly handsome. Bark cloth can be made from the inner bark of the tree's young branches, and its viscid, milky latex, which hardens on exposure to air, is a convenient glue. One exotic use for the latex is to put it on tree branches to capture birds. A ball of cotton soaked in it makes a caulking compound for boats. The latex of the breadfruit tree also makes an excellent medicinal plaster and has been used in the treatment of thrush, an oral fungus disease of newborns. Dried latex is a popular chewing gum in the tropics.

Despite the breadfruit tree's bounty, groves are fast disappearing from the tropical landscape. Breadfruit is being replaced by sugar cane and banana, both of which grow well under the same conditions. These cash crops figure prominently in the gross national product of developing countries, while locally consumed breadfruit gets scant recognition from economists. Haitian farmers prefer to grow bananas because the plant is continuously productive. At any given time, one or another plant in a banana grove provides fruit for household consumption or sale. The seasonal supply of breadfruit, on the other hand, is too great for kitchen needs, and the sale price is ridiculously low. Even picked in its green stage, the fruit can last for only three days without refrigeration.

At present, demand abroad is too low for the excess breadfruit crop to be exported like the banana. The fresh breadfruit occasionally seen in some fruit markets in the United States (such as the Hispanic market under the railroad viaduct uptown in New York City), is flown in from the Caribbean. (Attempts to grow breadfruit in southern Florida have not met with success, apparently because of occasional damaging frost and the less humid climate.) An excellent flour can be made from the breadfruit, but so far no one has produced it commercially so that it might be exported.

The trend away from breadfruit is unfortunate. Although bananas are among the most prolific of food crops (yielding, per area cultivated, forty times as much carbohydrate as the potato), the breadfruit tree is still more productive. A well-watered tree bearing twice a year yields about 1,000 breadfruits, each weighing about six pounds. The tree may occupy an area of about 800 square feet. The same land surface could accommodate sixteen banana trees, each yielding annually one banana stalk of 50 pounds, a total of only 800 pounds.

In order to be profitable, bananas and especially sugar cane must be grown in large areas. Perhaps a niche can be found for the breadfruit in scattered corners of the tropical landscape, even in urban backyards. Despite association with a negative past, both the seedless and seeded forms of *Artocarpus altilis* deserve to enjoy a renaissance. As Joseph Banks wrote, "If a man should in the course of his lifetime plant 10 such trees which if well done might take the labour of an hour or thereabouts he would as compleatly fulfill his duty to his own as well as future generations." □

Mary Grierson: Na Lima Kokua, Pacific Tropical Botanical Garden

Caterpillars are the food of choice for chickadee nestlings, fledglings, and nesting adults. Wintering birds eat berries and conifer seeds and inspect twigs and bark for animal foods such as insect eggs and pupae.
Irene Sacilotto

The Tiniest Established Permanent Floater Crap Game in the Northeast

Unattached black-capped chickadees roam among regular flocks, waiting for a lucky break

by Susan M. Smith

All winter long, black-capped chickadees have been among the most common visitors at bird feeders over much of the Northeast. Now, as spring arrives, these familiar little birds usually disappear from the feeders, almost as though they have left the area.

Actually, these chickadees are year-round residents over most of their range. The birds don't leave their winter neighborhoods, but abandon the feeders as they switch diets to their more natural fare of caterpillars and other insect food. At the same time, they adopt a different social organization. They are preparing for the breeding of the next generation, the crucial act of survival for all species. In the coming months the successful ones will be frantically feeding clutches of five to nine nestlings—extending the black-capped chickadee lifeline into the uncertain future.

Studying chickadees is addictive—I've been hooked on them for years. My current study, begun in 1979, involves banding as many local chickadees as possible each fall with unique combinations of colored plastic leg bands. This allows me to tell individuals apart at a glance.

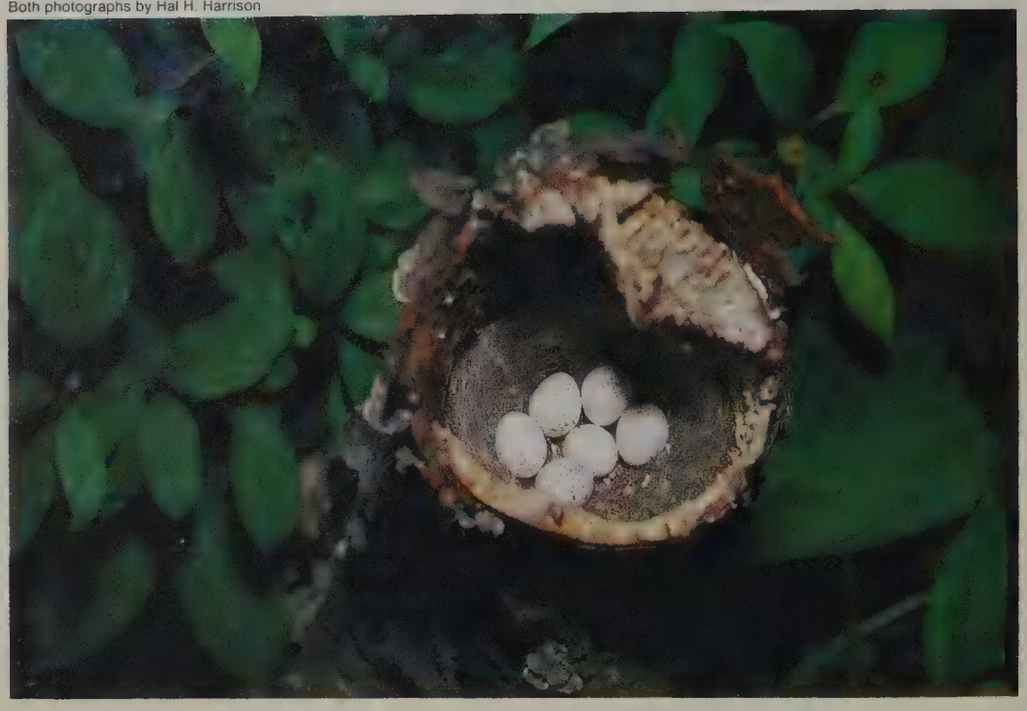
My western Massachusetts study area is a wooded residential district, well supplied with feeders. It includes some old deciduous forest and is bordered on one side by an old field. Since the chickadees breeding in the area are nonmigratory, the birds and their social organizations can be studied year-round.

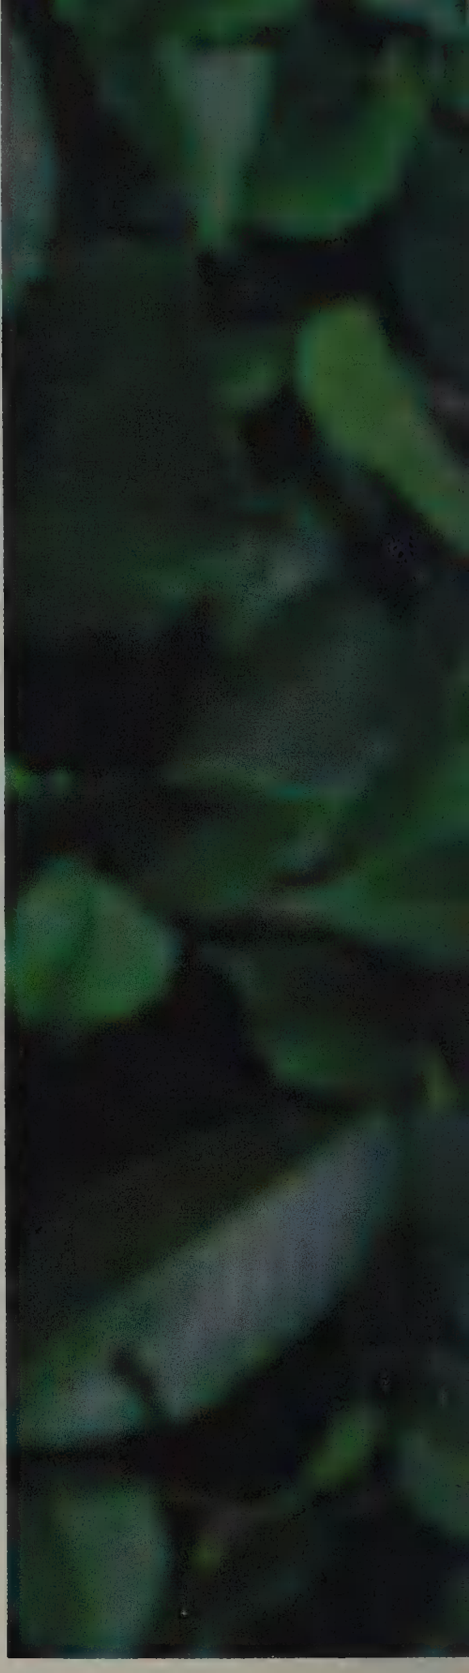
In winter each chickadee adopts one of two life styles: they are either regulars, always found in the same flock where I originally caught them, or floaters, which range among three or four flocks. What influence, I wondered, does the behavior of floaters have on the social patterns of black-capped chickadees?

In the spring and summer, chickadees live in monogamous breeding pairs. Each pair of successful breeders stakes out and defends a territory against all other black-capped chickadees. Territories, up to one-fourth of a square mile in my area, must contain an adequate supply of natural food, such as caterpillars, for both adults and nestlings. They must also have at least one suitable nest site, typically a rotten tree stump where chickadees can dig out a hole for their nest. The entrance is usually on the side of the stump, although it is not uncommon for it to be on the top. Both sexes share in the excavation duties; often several potential sites are dug out before the final selection is made. Only the female builds the nest, although her mate often accompanies her closely while she works. When the clutch is completed, the

A black-capped chickadee, right, pauses watchfully at its nest site, the stump of a dead birch. Both males and females typically excavate such cavities, where the females usually brood a clutch of five to nine eggs, below. Pairs that dominate the flock during the winter are most likely to secure breeding territories in the spring.

Both photographs by Hal H. Harrison





female incubates, while the male defends the territory and brings food for his mate on the nest. When the young hatch, both parents bring food for their nestlings. After leaving the nest, young chickadees generally remain dependent on their parents for up to four weeks before dispersing, often moving several miles away before settling down on their own.

At the end of the summer, a major social shift occurs. The older birds, undergoing postbreeding molt, no longer defend their breeding territories but gradually come together with several of the newly fledged young chickadees to form flocks. These flocks will occupy and defend a flock territory (usually two to three times the size of a breeding territory) against neighboring chickadee flocks. They persist through the winter until the birds break up into breeding pairs the following spring.

Floaters exist at all seasons within this alternating social system, but I've concentrated on floaters in the winter flocks because every young chickadee must enter the system as these flocks form in the fall.

Both regulars and floaters had a clear-cut linear pecking order in each of my study flocks. To determine these hierarchies, I considered chickadee A to be dominant over B if any of four things occurred: A supplants B (A arrives and takes over B's perch, forcing B off); A chases B; B tries unsuccessfully to supplant A; A and B arrive at a feeder simultaneously and A takes a seed first and leaves before B eats. I gathered most of my data on hierarchies at feeders, since in an earlier study I had found that chickadee peck orders away from feeders were the same as those at feeders.

This simple test, while only a brief episode in the life of a chickadee in nature, told me a lot about a bird's status. (In fact, the test isn't all that simple since I had to identify two birds from their bands, ascertain what happened during their interaction, and determine which bird went off with or without a seed—all in a few seconds through binoculars—before I could tell which bird was dominant.) After ranking the birds in an area, I had a better idea of their chances of surviving, of the likelihood of their breeding, and of the relative ranks of regulars and floaters.

Most chickadees in a flock are regulars, which spend the entire winter within a single flock. The twenty-three flocks I studied over five winters contained anywhere from six to fourteen regulars, with an average of nearly ten. The regulars apparently paired right from the start. Pairing, even by young birds, may actually be an integral part of autumn flock formation. I came to this conclusion because first, a twenty-three flocks had an even numb of regulars by the time the last regular ha joined; second, all flocks had even se ratios; third, the dominance rankin strongly suggested pairing; and fourth, o servations of spring breeding confirme the identities of specific pairs. Thus flock of ten regular members is probab made up of five pairs of chickadees.

There is another, grimmer fact abo these winter flocks. The area defended b a typical flock of five pairs is not larg enough for five breeding territories. Thu

even if all ten birds survive, only the few highest-ranked pairs will breed in the area at the end of the winter. Most of the others will be driven away. A few may find undefended areas to settle in, but most of the rest will not get to breed.

Several winter floaters associated with each of my flocks. They typically ranged among three or four flocks, with an established place in the peck order of each. They were all young birds that had never bred in the area before. Usually I found floaters either with a flock or moving singly, silently, and quickly from one flock to another. Floaters always ranked below all of the regulars of their sex in each flock hierarchy. Significantly, as floaters, they showed no sign of pair bonding.

Floaters also had dominance relationships, and their relative ranking always remained the same—if one bird ranked above another in one flock, it would remain higher in any other flock where both appeared.

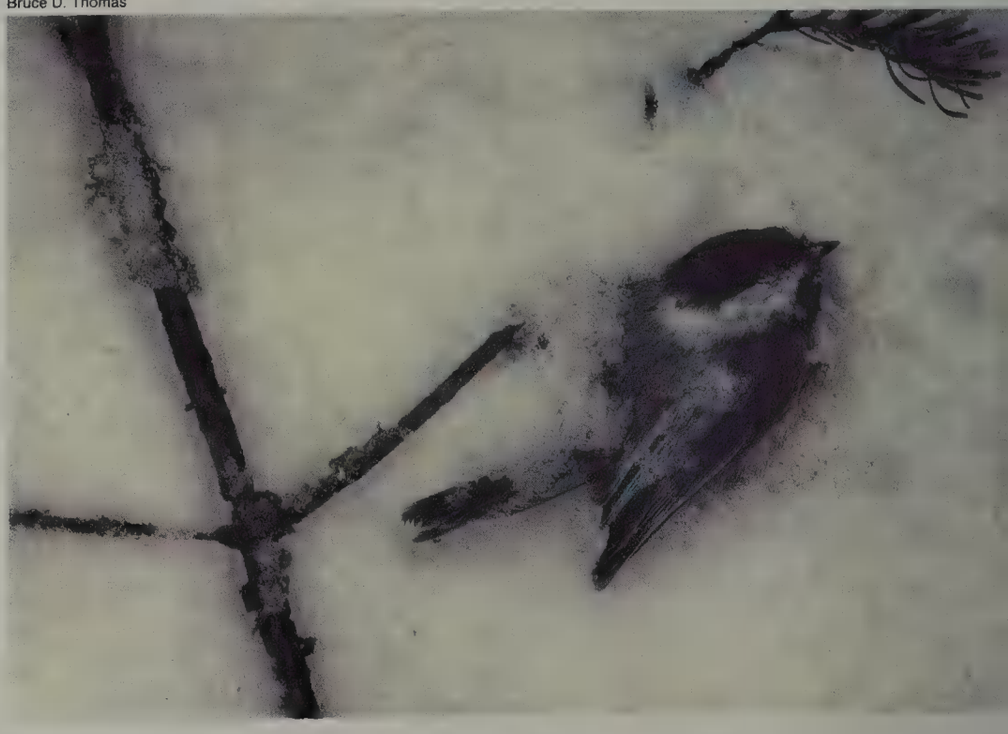
What possible interest can we have in these low-ranked birds that don't even have pair bonds? At first glance they do appear to be unsuccessful, irrelevant birds. But wait. What happens when the alpha male in a flock disappears—maybe picked off by the local cat or by a sharp-shinned hawk (my two highest sources of mortality)? Will the beta male take over? No. Instead, the highest-ranked male floater moves in as the dominant male of the whole flock. Similarly, if a high-ranked female vanishes, her place in the peck order is rapidly taken by the local dominant female floater, which settles down immediately and starts acting like the regular she has, in fact, become.

Over the past five winters, I have seventeen records of banded floaters—eleven females and six males—that succeeded in getting a regular's slot in this manner. All

John Sha

Below: In winter, chickadees may freeze to death or starve. Other common causes of mortality are predators, such as sharp-shinned hawks and house cats. Right: Just before spring, the flocks may start breaking into pairs, with males attending closely on their mates. Chickadees are for the most part monogamous; winter flock membership is made up of several mated pairs joined by a few unattached floaters.

Bruce D. Thomas



seventeen birds not only gained high-ranking positions with a regular mate in a flock but also obtained a breeding territory the following spring. Each bred with the mate of the bird it replaced.

Why don't such vacancies get filled by the next highest regular? How can the beta male sit by and allow a previously lowly floater to take over as the alpha male? When the floater inserts itself into the flock hierarchy and settles down, all intact pair bonds among the surviving regulars remain unchanged. Most regulars may actually be locked into their rank by their pair bonds, so that only the unpaired floaters are free to move in when a high-ranked opening occurs.

By far the most common sort of substitution (fifteen of my seventeen records) was a simple process involving just three birds: the regular that died, its mate, and the floater that took over the dead bird's slot. In two other cases, however, the process was a bit more complicated. If a flock contains at least two intact pairs of old, high-ranked birds, and if a member of the higher-ranked pair vanishes, its slot may be taken not by a floater (although one will try at first) but rather by a member of the second-ranked old pair. Then the floater will take over the vacant second-ranked slot.

Floaters do not fill a vacancy every time a regular disappears. First of all, no floater–floater pairs are formed: if the mate of a newly inserted floater dies, a second floater will not insert and pair with the first; instead, the first will take on its old rank again and resume floating. Secondly, floaters will only move in when a high-ranking bird dies. In the five winters of the study, thirty-eight regulars below the top three ranks of their sex lost their mates; all thirty-eight widowed birds remained mateless for the rest of the winter. These low-ranking positions apparently are less desirable because only the top two or three pairs in a flock will get a territory and breed in the spring (the ultimate goal of every chickadee).

If only the top few pairs in a flock get a breeding territory, why are there any lower-ranked regulars in the flocks at all? These low-ranked birds do have some chance of attaining a higher rank by spring. If both members of a top-ranked pair disappear in a winter, they will not be replaced by floaters because two floaters do not form pairs. Instead, the lower-ranked pairs all move up one notch in the hierarchy, so the fourth-ranked pair becomes third, greatly increasing its chances of breeding in the spring.

Soon after they become independent of their parents, young chickadees must enter the complex social system of their species. To be truly successful, a young chickadee should end the winter as a high-ranked regular, since normally only regulars can gain local breeding territories come spring. Potentially there are several options that can lead to this goal.

By far the easiest road to success is to enter as a high-ranked regular in the fall. Every summer a few local breeders die, leaving high-ranked slots that will clearly be the first to be filled in the fall. When all the top slots are taken, arriving young chickadees must choose among three other possibilities: entering as low-ranked regulars, high-ranked floaters, or low-ranked floaters. After the top slots are filled, the next to go are usually those of the high-ranked floaters. (Five of my successful floaters were banded and moving regularly from flock to flock well before all the regulars had joined the flocks. Later arrivals settle in as low-ranked regulars. The last to come join as low-ranked floaters, but some years no birds enter flocks at this level.

This sequence reflects the decreasing likelihood of gaining a breeding territory. The lucky young chickadees that get to enter as high-ranked regulars have it made—even if a mate dies, it will simply be replaced by a floater. For high-ranked floaters to succeed, a suitable opening must appear in one of their flocks, and the widowed bird that becomes the new mate must survive the winter. Success for low-ranked regulars depends on both members of at least one pair in their flock dying in the same winter. Low-ranked floaters can succeed only if something (mortality and/or successful insertion) removes all higher-ranked floaters and a suitable opening occurs.

Over the past winter, two sorts of chickadees probably visited suburban bird feeders: the regulars, which never stray from a few neighboring yards, and the floaters, which may range from feeder to feeder over many blocks. They each have a different strategy, but their goal is the same. The eventual winners may appear in your yard next summer, busily gathering caterpillars for their hungry offspring. □

In perfecting its
forgotten to lea

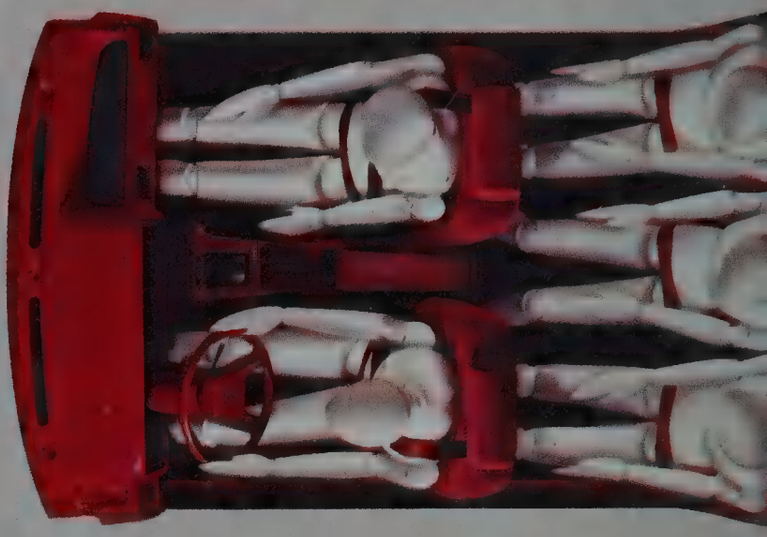
You'd have to be a dummy not to appreciate what's inside a Topaz.

There's room.

89.3 cubic feet of interior space that's so intelligently designed there's room not only for 5 people to sit.

But, thanks to an engineering discipline called ergonomics, room for 5 people to sit comfortably.

And room for the things 5 people like to bring with them.



Because Topaz was designed around the way the human body naturally bends.

Not the way metal does.

Of course, Topaz seeks to reward the drive as well as his passengers.

With mud-churning, snow-throwing front-wheel drive.

Bump-eating inde-pendent 4-wheel suspension.

Lincoln-Mercury Division Ford

Get it together—buck

hape, we haven't e room for yours.

And so much torque that even at low rpm evels in stop-and-go driving, its fuel-injected engine responds without hesitation.

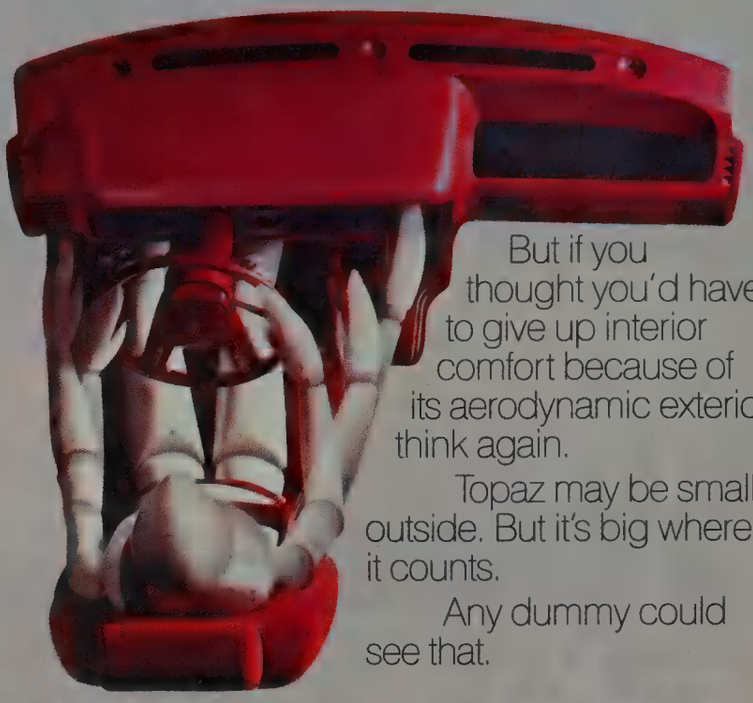
Topaz has also brought the unusual into he realm of everyday experience.

With an engine computer capable of processing more than a quarter of a million commands per second, Topaz adjusts its engine's functions continuously.

And, in the process, maximizes combustion efficiency.

Certainly the 1985 Topaz is an aerodynamically advanced automobile.

(In fact, if you'll call us at 1-800-MERCFAX, we'll send you a free 1985 Topaz catalog with a complete explanation.)

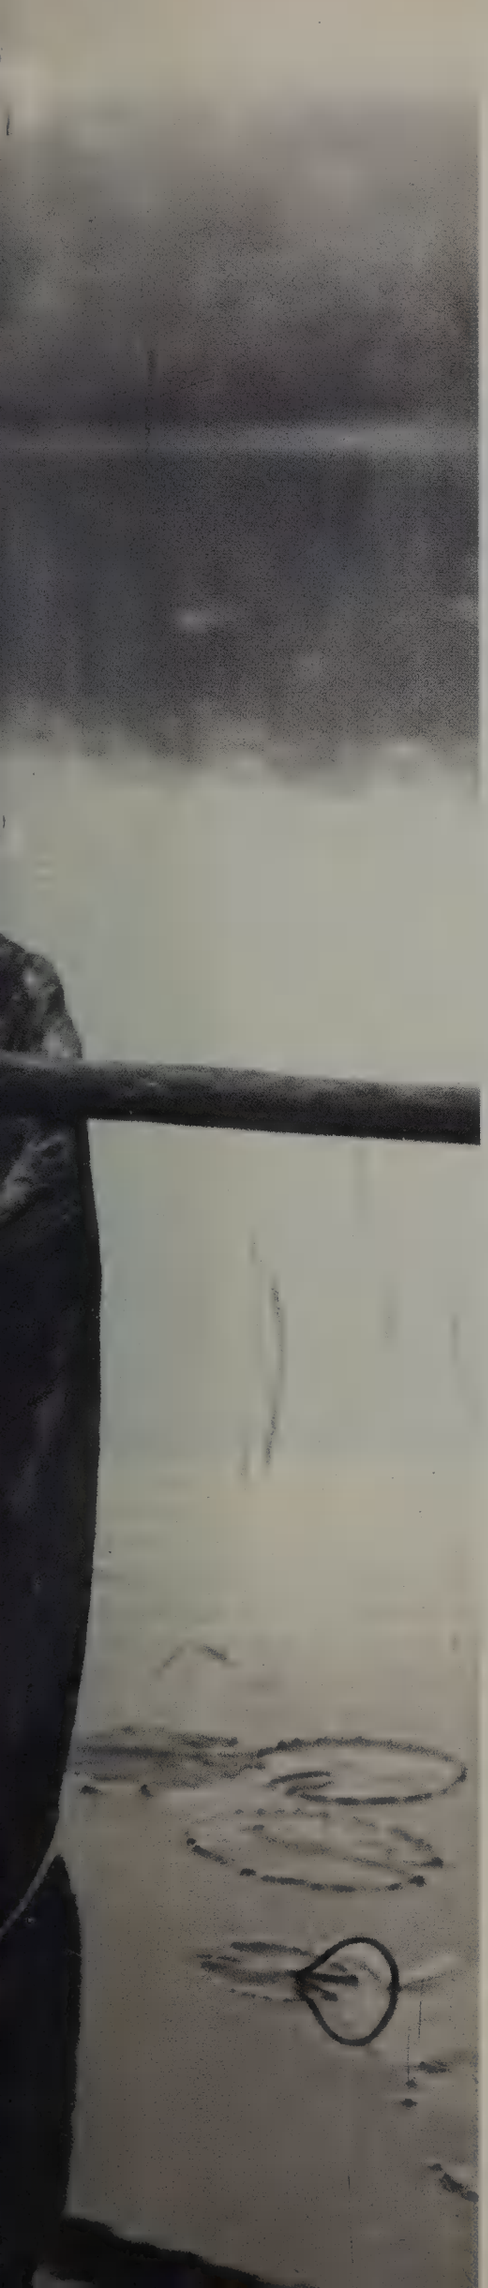


But if you thought you'd have to give up interior comfort because of its aerodynamic exterior, think again.

Topaz may be small outside. But it's big where it counts.

Any dummy could see that.

Mercury Topaz



Bearing Witness

The Lacandon Maya's traditional culture survives in the images of Gertrude Blom

by James D. Nations

In 1939, Swiss-born political activist Gertrude Duby gained release from a fascist detention camp in prewar Europe and emigrated to Mexico to begin a new, nonpolitical life as a journalist. Instead, she became one of Mexico's most outspoken advocates for Indian rights and for the conservation of their tropical forest environment. Simultaneously, she emerged as one of Latin America's finest documentary photographers, producing images that illustrate four decades of change among Mexico's indigenous peoples.

In Chiapas, the southernmost state in Mexico, Duby met and married Danish archeologist Frans Blom. Together, they explored and mapped the Selva Lacandona, Mexico's largest tract of tropical rain forest and home to the Lacandon Maya Indians. Gertrude Blom's respect for the Lacandones earned her their trust and admiration, and she began to document both their traditions and their reaction to the cultural threats of the outside world. Decades later, when economic forces began to threaten the survival of the Selva Lacandona itself, Blom began an ongoing struggle to protect the region's people, plants, and wildlife.

Today, at eighty-three, Gertrude Blom is the living conscience of the Lacandon jungle, reminding us of treasures lost and of what we still stand to lose. Alex Harris, director of Duke University's Center for Documentary Photography, describes her as "part journalist, social activist, and explorer, part anthropologist, photographer, and ecologist, and, it would not be an exaggeration to state, part legend."

When Frans and Gertrude Blom first journeyed on muleback through the Lacandon jungle in 1943, they explored a region blanketed by more than 5,000 square miles of virgin tropical rain forest. At the time, the only other people in the area were 250 Lacandon Maya Indians, a handful of mahogany loggers, a few teams of chicle gum gatherers and crocodile hunters, and an incipient trickle of immigrant Tzeltal farmers from the nearby Maya highlands.

Down every jungle trail the couple rode they found wilderness, pristine rivers, and an abundance of rain forest wildlife. Peccaries and pacas dashed across the trails at the sound of the approaching explorers. Flocks of parrots and scarlet macaws flew overhead toward mountains that had not seen outsiders in centuries. A million insects hummed and whined and buzzed. By night, tapirs, jaguars, and kinkajous roamed the jungle near the expedition's

Excerpted from *Gertrude Blom: Bearing Witness*, edited by Alex Harris and Margaret Sartor. Photographs ©1984 by Gertrude Duby Blom. Text ©1984 by Center for Documentary Photography, Duke University. Published by the University of North Carolina Press and used with the permission of the publisher.

campsites. And as dawn appeared, the forest stretched on forever.

Today, more than forty years after the Bloms' first expedition to the Selva Lacandona, the jungle is an entirely different place. Almost half of the forest has been cleared and burned, and much of the rest has been degraded by loggers, colonists, and ranchers. Thin Brahman cattle search for forage where ceiba trees once arched over jungle waterfalls, and felled mahogany trees weigh down logging trucks that ply the region's growing network of asphalt and gravel roads. Bulldozers tear paths through primordial vegetation in an obsessive search for petroleum, and leftover hippies step down from second-class buses to search for magic mushrooms in the debris of the Maya past.

Once the secret refuge of Maya heritage, the Selva Lacandona has become the frontier home of more than 150,000 immigrant farmers and 70,000 Guatemalan refugees from a neighbor's bloody war. The only remnants of the rain forest's unviolated expanses persist in a few inaccessible valleys and in the haunting photographs of Gertrude Blom.

The ignorance, greed, and progress of civilization have begun their final round of destruction in the Selva Lacandona. The politicians' dream to incorporate the rain forest into the national economy will soon bear fruit on eroded hillsides and in weeded, wasted valleys.

Gertrude and Frans Blom's expedition to the Lacandon rain forest in 1943 was not the only significant event that affected the Lacandones during the 1940s. That decade also brought about the most dramatic change the twentieth-century Lacandones had ever seen—the massive invasion of their rain forest territory by colonizing farmers from other regions of Mexico. In a program similar to the United States Homestead Act, thousands of Indian and mestizo peasants were exhorted by government agents to move into the Chiapas lowlands in search of land and new lives. Ironically, many of these immigrant families were Tzeltal and Chol Maya, the descendants of groups who had been forcibly removed from the region by colonial Spaniards four centuries before.

Maya ruins

The *kaho,* "the community dwellers," as the Lacandones called the invaders, established colonies throughout the uninhabited rain forest between the Lacandon settlements. They began to clear and burn the forest to raise corn, beans, chilies, squash, coffee, and cattle. The Lacandones—who were reluctant to live near even nonrelated members of their own

group—were not pleased with these new arrivals. They drew their settlements into tighter patterns, concentrating on the rivers and lakes in the center of the jungle.

Unlike the Lacandones, the new immigrants raised pigs and cattle for sale in commercial markets. Such activities—and the sheer number of new people in the region—placed harsh burdens on the rain forest environment. Eventually, the immigrants' activities began to eradicate the forest itself. Instead of allowing agricultural plots to regenerate in natural forest, the Tzeltal and Chol Maya seeded their abandoned milpa plots in pasture grasses for cattle.

The final blows to the forest began during the 1960s, when the Mexican government began a program of road construction aimed at extracting the jungle's mahogany and tropical cedar trees. These logging roads pierced the core of Lacandon territory and triggered another massive influx of colonizing farm families. As this second wave of immigrants ate through the forest, wealthy Mexican cattlemen followed in their wake, buying up the families' cleared plots to create large ranches. Supported by generous bank loans, these colonists-cattlemen joined the state's politicians in envisioning the rain forest as one vast cattle ranch, and they set about turning that vision into reality. Where toucans and tapirs had lived only months before, the ranchers produced beef cattle for export to Villahermosa and Mexico City. More than any other act, the introduction of commercial cattle ranching into the Selva Lacandona spelled the death of traditional Lacandon society and of their rain forest environment.

The in-migration of farmers and cattlemen forced the Lacandones to abandon their isolated family settlements and brought them face to face with the modern world. During previous centuries the Lacandones had learned that by concealing their settlements they could avoid unnecessary contact with outsiders. But techniques acquired in earlier times—milpas and houses hidden behind a wall of jungle, trails that seemed to disappear—proved futile against the onslaught of change during the 1960s. As the region's population exploded, constant contact with outside groups became unavoidable. During the 1970s government relocation teams searched out the Lacandon families still living in isolation in the forest and moved them into the settlements of Mensäbäk and Najá in the northern jungle and Lacanjá Chan Sayab in the south.

Through nò choice of their own, the Lacandones had lost the isolation that, for centuries, had protected their lives and their traditions. Simultaneously, the Lacandones began to lose the rain forest ecosystem that had supported both the old ways and their lives.

Today's adult Lacandones are the transition generation in this dramatic wave of change. Their predecessors lived in a world uninterrupted by radios, airplanes, and chain saws. Where their fathers hunted jaguars with bows and arrows, their children now drive rattling trucks down muddy jungle roads. A Lacandon man in the 1980s may begin his day with a chant as old as the Maya themselves and end it hunched over a battery-powered record player blaring raucous mariachi music in a language he does not understand. In a very real sense, the Lacandones of today have inherited both the legacy of the ancient Maya and the dubious gifts of the twentieth century.

Gertrude Blom has captured this generation of Lacandones in a sequence of photographs that allows us to see how changes have affected them through the decades. In watching these people adapt, we see the effects of our civilization on traditional peoples throughout the world. In turn, their transformation teaches us lessons about ourselves, for we too are a transition generation.

When Blom began to photograph the Lacandon Maya, men still hunted forest animals as they had for centuries. They continue to hunt today, but they use rifles rather than the bows and arrows of their fathers. Lacandon women still grind corn as they have for centuries, but—except for religious ceremonies—they use aluminum grinders manufactured in distant cities. In recent years, some men have cut their hair in Western style and traded their tunics for polyester shirts and pants, but most still dress in the traditional white cotton *shikur,* even though the cloth comes from the city. In some Lacandon settlements, families have exchanged the gods of rain, fire, and forest for the flashlight slide shows of evangelical missionaries. Other families remain hidden within the forest, burning copal incense and small rubber figures to the silent Maya gods.

Modern Lacandones remain divided into two distinct groups, northerners and southerners, so called because of their general location in the Selva Lacandona. Most southerners live today at Lacanjá Chan Sayab, although a few hang on at the older community of San Quintín. Northern Lacandones live on the shore of Lake Najá and near Lake Mensäbäk and in a few isolated family settlements scattered across the northern Selva Lacan-

Deforested hillside

dona. Counting all the families of both groups, the Lacandones number slightly over four hundred people.

Lacandon men let their long, black hair fall over the shoulders of their white tunics. Northerners distinguish themselves from southern men by cutting bangs across their foreheads. Southern women leave their hair long and flowing and wear colorful versions of the men's white robes. Northern women pull their hair back in a single braid decorated with the yellow breast feathers of the toucan, an exotic rain forest bird. They wear a shorter version of the men's white tunic over a colorful skirt decorated with ribbons. For both men and women, the longer sleeves and hem of the southerners' tunics give outsiders a clue to their origin and provide the source of one of the northern Lacandones' names for their southern relatives—*chukuch nok,* "the long clothes."

Although many northern and southern Lacandon traditions are similar, it is religion that most differentiates the two groups. Religious beliefs in north and south had always varied, but southerners abandoned the traditional Maya gods during the first half of the century, when their leader died in a devastating yellow fever epidemic and his successors failed to effect a smooth transition in the chaos that followed. In 1957, after thirteen futile years of missionary work aimed at converting the northern Lacandones of Najá, an American Bible translator set up camp among the southerners. His efforts among the disoriented southerners were rewarded by the mass conversion of almost all the families at Lacanjá.

Recent missionary efforts have made inroads among the northern Lacandones as well. During the mid-1970s, a visit by a Yucatec-speaking Maya from northern Yucatán came shortly after the death of the Mensäbäk leader's only son. The missionary exhorted the men to reject their old religion. "Give up your gods and devil worship and your children will not perish," he promised. In the same breath, he promised a gasoline-powered electric generator, a road, and visits by a doctor. The settlement's leader accepted the promises. Most of the settlement followed, although a few families slipped into the jungle to resume their chants and prayers. Today in Mensäbäk, a Seventh-Day Adventist church stands on the tallest hill in the community, and the children sing "Jesus Loves Me" in Lacandon. They scoff at the children of families who have not converted and call their parents "animals in the forest."

Men with hunting rifle

Lacandon man in a jungle thicket

Lacandon men in traditional dress

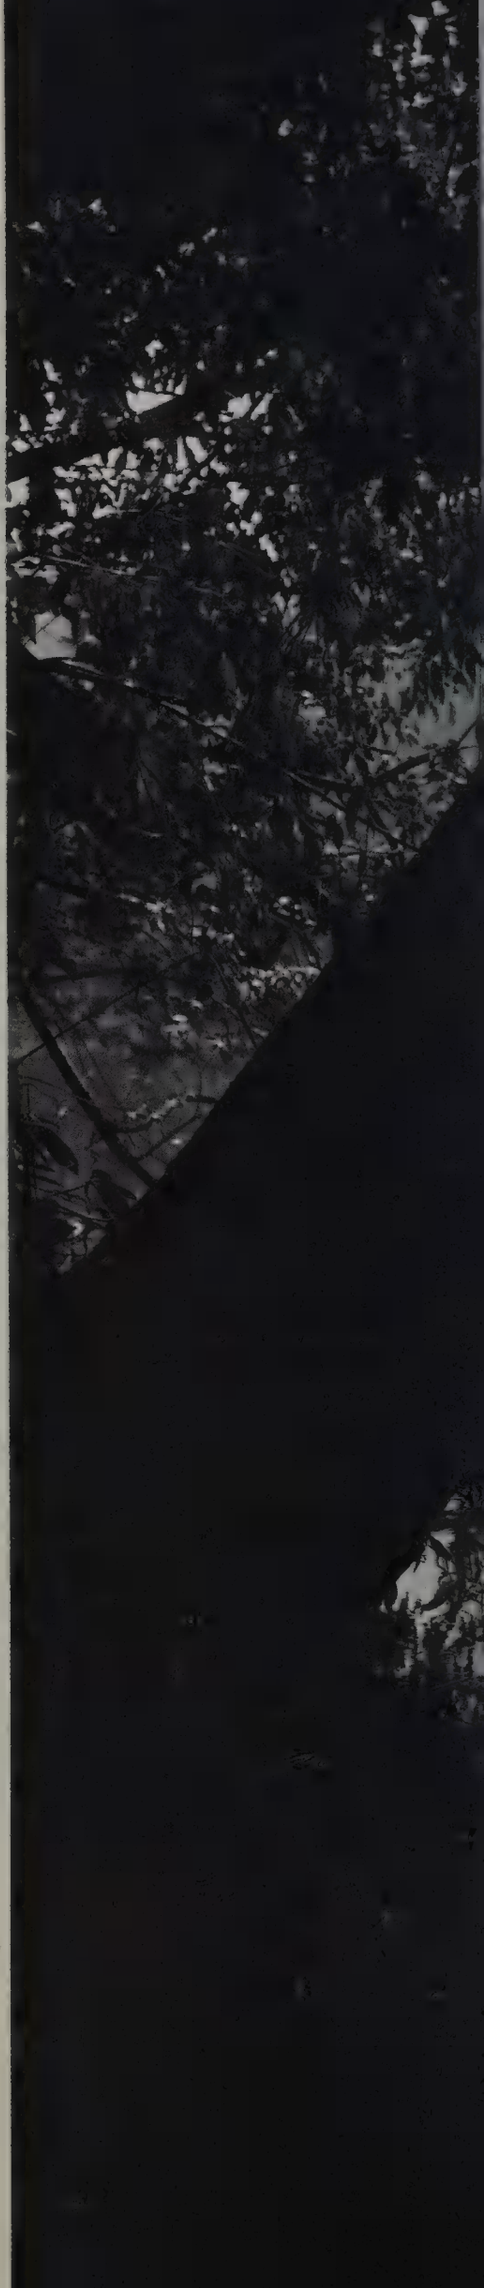
Only a few isolated families and the ıorthern Lacandones of Najá maintain he traditional Maya religion. Led by Chan K'in Viejo, the octogenarian *t'o'ohil* the great one) of Najá, they have resisted ɔoth missionary efforts and the tempta- ions of the technological world. When ɔmeone falls ill or when it is time to pay he gods with *balche'*, a mildly intoxicat- ng drink made of tree bark and the fer- nented juice of sugar cane, they lift clay god pots down from the sacred shelf of the god house and place them gently on ma- ıogany boards covered with fresh-cut ɔalm fronds. Chan K'in begins to chant in ı resonant voice: accusing, promising, of- fering to pay the gods with incense and small human figures molded of rubber from trees in his garden plot. He leans ɔver the tiny rubber figures and whispers, "Wake up, wake up." Then he places hem on flaming copal incense in the god ɔots, to be consumed and carried to the af- erlife to pat out the gods' tortillas and serve them food and corn gruel.

Thirty years after Gertrude Blom's first rip to the Selva Lacandona, I stood on the nud-and-grass airstrip in the Lacandon settlement of Mensäbäk and watched a Cessna bush plane bounce to a halt before ı group of thirty Lacandon Maya men and women. The Lacandones waited motion- ess while three Mexican businessmen emerged from the plane like space travel- ers from a time warp. Standing at the edge of the rain forest, with bare feet and white cotton tunics, the Lacandones looked more like figures from a lost Maya codex han like a reception committee on a jun- gle airstrip.

After the businessmen had perfunc- orily greeted the Lacandones, a buxom young woman in high heels and polyester dress stepped down from the plane and be- gan snapping photos with an Instamatic camera. The businessmen pulled bolts of cheap cotton cloth from the plane and tore them into sections to hand out to the Lacandon women. Then, amid all the hub- bub, they lifted thick documents from a briefcase. None of the Lacandones could read and only a few spoke Spanish, so no time was wasted on fine print or negotia- tions. After the Mexicans' hurried ex- planation, the Lacandon men lined up and eagerly affixed their thumbprints to the contracts. The conference completed, the group piled back into the plane and took off for the settlements of Najá and La- canjá, where they would repeat the scene and close two more deals.

Twelve months later, with legal con- tracts filed, the government-owned log-

Lacandones in dugout canoes



ging company that the businessmen represented bulldozed roads toward the Lacandon communities and began to rattle the hills with chain saws and falling trees. During the months that followed, they extracted thousands of mahogany, tropical cedar, and ceiba trees from the Lacandon lands. According to the foreman of one logging team, in a single period of twenty days his group wrenched two million dollars worth of logs from the rain forest. The Lacandones grasped the full meaning of the contracts they had signed when workmen began to log the hillsides at the edge of their settlements.

Not all the Lacandones had been so quickly duped into selling their rain forest heritage. Asked by government officials to sign the logging contracts, Chan K'in Viejo advised them that the jungle's mahogany trees were not his to sell. "I didn't plant the trees," he said. "They're God's," meaning Hachäkyum, the major Lacandon deity. "Go ask him."

But of course they didn't. Instead, through a suspect political manipulation, government agents made the old man's son the *presidente* of the Najá settlement and obtained his signature in exchange for a truck and a headful of promises.

Watching this greed-fueled destruction of the Lacandon rain forest was my introduction to the problem of tropical deforestation. I later learned that the devastation of the Selva Lacandona is only a small part of a much larger process of destruction—a process that threatens to eliminate much of the world's tropical rain forest, its peoples, animals, and plants, before the turn of the century.

Throughout the world, almost 40,000 square miles of tropical rain forest are cleared and burned each year in the name of survival, progress, and profits, and another 40,000 square miles are degraded by logging, fires, and livestock grazing. The repercussions, says biologist Edward O. Wilson, will be worse than "energy depletion, economic collapse, limited nuclear war, or conquest by a totalitarian government. It is the folly which our descendants are least likely to forgive."

Ironically, we know very little about what we are destroying. Only one out of six tropical organisms has been described and named by scientists. The world's remaining rain forests contain twice as many unknown species as scientists have examined and classified since Linnaeus began the process 230 years ago.

Some of the reasons for conserving the world's tropical rain forests are economic—new medicines, food crops, industrial fibers, gums, spices, dyes, resins, oils, lumber, cellulose, and wood biomass. On the other hand, some of the reasons are ethical or aesthetic. Ecologically conscious individuals usually require only one argument about why we should preserve large sections of the world's tropical rain forests: Rain forests have enriched the earth for more than one hundred million years, they are the cradle of terrestrial evolution, and they are "the richest and most exuberant expression of life on land," as ecologist Lawrence Hamilton has noted. As the home of almost half of the earth's plant and animal species, rain forests form a crucial element in our global ecosystem.

Finally, some of the reasons for conserving rain forests are humanitarian. Gertrude Blom's writings, speeches, and photographs bear witness to one culture being lost to the destruction that is overwhelming our planet's tropical forests. □

Future Farmers of the Sea

Tiny marine animals called foraminifera are waiting in eddies for a new geologic age to arise

by Pamela Hallock

Countless billions of tiny, delicately shelled creatures known as foraminifera have inhabited the seas of our planet beginning more than 500 million years ago and persisting to today. Hundreds of lineages of forams have evolved, diversified, and gone extinct through the geologic ages.

Forams are found everywhere in the oceans, from deep beneath the Arctic icecap to shallow tidal pools in the tropics. Often smaller than grains of salt, forams can be found attached to rocks and seaweed, where they capture food by straining bacteria or microscopic plankton from the water through sticky strands of protoplasm known as pseudopods. Many forams move freely, though slowly, along the sea bottom, using their pseudopods to pull themselves along. Others live as plankton, drifting freely in the waters of the open ocean.

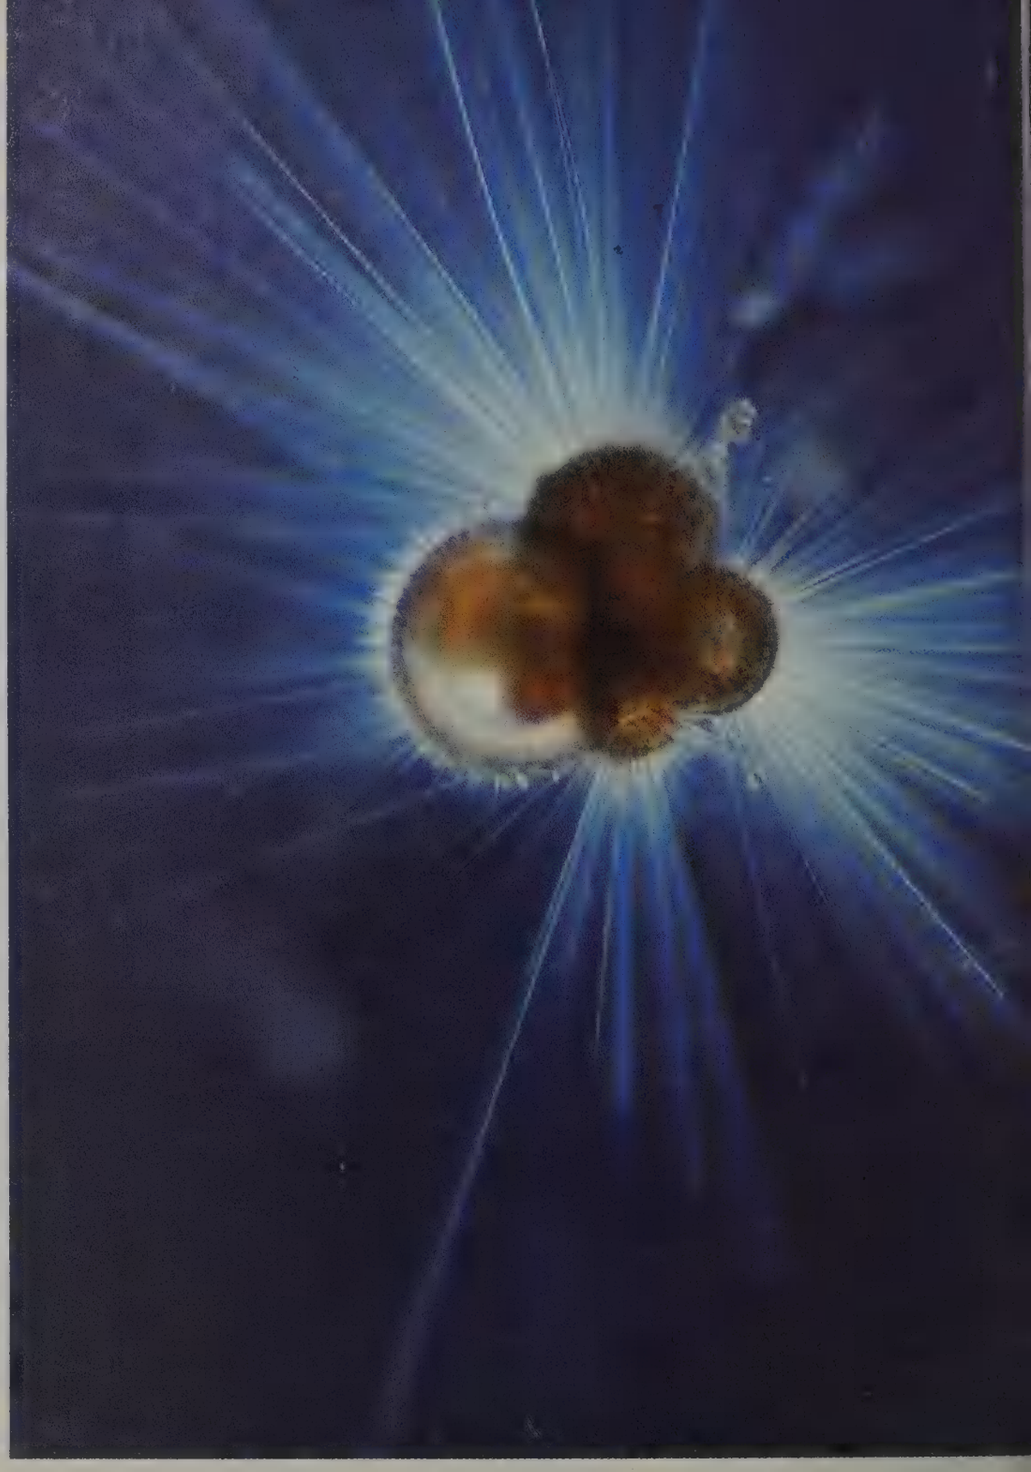
In the late eighteenth and early nineteenth centuries, scientists thought that forams were minute relatives of the chambered nautilus. Not until the mid-1800s did they realize that the living foram is very much simpler than a nautilus—that it is actually a single-celled, amoebalike protozoan.

Alcide d'Orbigny, one of the first paleontologists to study microscopic fossils, recognized that the remains of these tiny creatures were plentiful in many types of rocks and predicted that they could be used to correlate ages of rocks in widely separated regions. In the early 1900s, Joseph Cushman pioneered the use of fossil forams to tell the relative ages of rocks encountered in the course of drilling oil wells. Because of their importance for economic geology, foraminifera have been carefully described and cataloged. The American Museum of Natural History has one of the most extensive collections of these tiny fossils, and its voluminous technical publications about them are purchased by oil companies and geology libraries throughout the world. But most studies have stopped once the animal's fossils have been described, named, and dated. Until recently, almost nothing was known about the natural history, the ecology of most forams.

Foraminifera may be smaller than grains of salt or as large as poker chips. Less than one-tenth of an inch in diameter, this foram was photographed at 600 times magnification through a scanning electron microscope.

© Manfred Kage; Peter Arnold, Inc.

© Manfred Kage; Peter Arnold, Inc.



In the past two decades, however, scientists from several disciplines have begun to study the life histories of forams, particularly the larger species that survive today. As so often happens, these seemingly simple, single-celled creatures turn out to lead marvelously complex lives, and their histories cast light on some of the most profound questions of evolution.

One special group, known as the larger foraminifera, has received some of this newly focused attention. Larger forams are structurally more complex than the smaller varieties and range in size from that of a rice grain to that of a poker chip. (For a foram, being poker chip size is comparable to a marine mammal being blue whale size.)

Larger forams today are found mostly in warm, clear, shallow waters in the tropics and subtropics, often living on seaweeds or seagrass. Most fossil larger forams are found in limestones of shallow-water origin. In fact, the nummulitic limestones, from which the pyramids of Egypt were constructed, consist primarily of larger foraminifera shells.

In 1970, when I was a graduate student in oceanography at the University of Hawaii, geochemist Keith Chave suggested I use my background in biology to study rates of sediment production by forams. (The problem is of geologic interest in Hawaii and on other islands of the Pacific because foram shells make up so much of the sand in the coral reefs and beaches there.) At about the same time, several other scientists—in the United States, Europe, and the Middle East—were, independently of one another, beginning to study various aspects of the larger living forams. One result of all these studies is the discovery—which fossils would not reveal—that almost all large forams are hosts to algae. The outer, translucent chambers of the shells are, in a sense, small greenhouses for crops of these single-celled plants.

Nitrogen and phosphorus, essential nutrients required for growth by all plants, are present in the forams' waste products. These wastes provide the symbiotic algae with a continual source of nutrients. In turn, algae photosynthesize—that is, use the sun's energy, carbon dioxide, water, and foram wastes to make sugars and other organic matter. Keeping some of what they produce for themselves and giving up the rest, the algae provide their hosts with an internal food source. In addition, because algae take up carbon dioxide and give off oxygen, they serve as kidneys and lungs for the forams. These functions may have been crucial as forams became larger, since they lacked respiratory and excretory organs of their own.

The algae–foram relationship is the key to answering many questions about larger foraminifera. The easiest is, why do larger forams normally occur in relatively shallow water or in limestones of shallow-water origin? The answer is that their algae need sunlight, and sufficient light for photosynthesis penetrates to a maximum depth of about 500 feet (and then only in extremely clear water). Other difficult puzzles about these foraminifera—concerning their feeding methods, size, complexity, and episodes of evolution and extinction—require more consideration.

For most animals that capture prey, the captured organisms supply all the energy needed to live and grow. But larger forams capture bacteria and plankton primarily to supply nitrogen and phosphorus to the algae living within them. Under what circumstances is that symbiotic way of life advantageous? One answer: when the supply of dissolved nitrogen and phosphorus is very low.

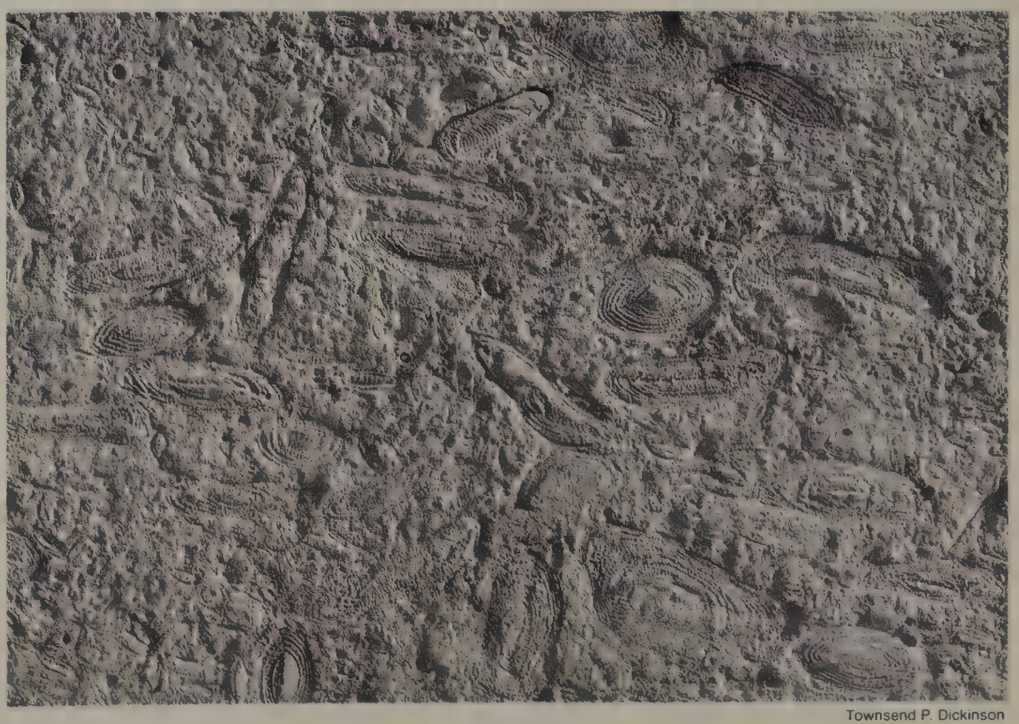
In the marine realm, the richest environments are near river mouths or in areas where upwelling currents bring dissolved nitrogen and phosphorus to the sea surface. Most surface waters of tropical and subtropical oceans, however, are far from

Forams use strands of protoplasm to capture food and to move about. Left: Shells of some species may be covered with delicate spines. Below: The whorled shells of larger forams are common components of sand on Kahuku beach, Hawaii. Bottom: Forams flourished during geologic eras when sea levels were high, and their fossils dominate many limestone strata. Foram fossils are easily seen in the base of the New York City monument known as Cleopatra's Needle.

Rudolf Röttger

these major sources of dissolved nutrients. Interestingly, many of the organisms that flourish in nutrient-poor areas—from forams of the open ocean to corals of the Caribbean shallows—are hosts to algae. The question is, just how does this symbiotic relationship improve an animal's ability to nourish itself?

When an animal with algal symbionts captures another organism for food, the animal in the association digests that food, using perhaps 10 percent or less for growth. The other 90 percent or more is burned in respiration to provide energy needed to live and capture more food. The nutrients originally incorporated in that 90 percent are broken down into waste products. The algae can use those "waste" nutrients and sunlight to produce by photosynthesis nearly as much organic material as the host used in metabolism. Even if

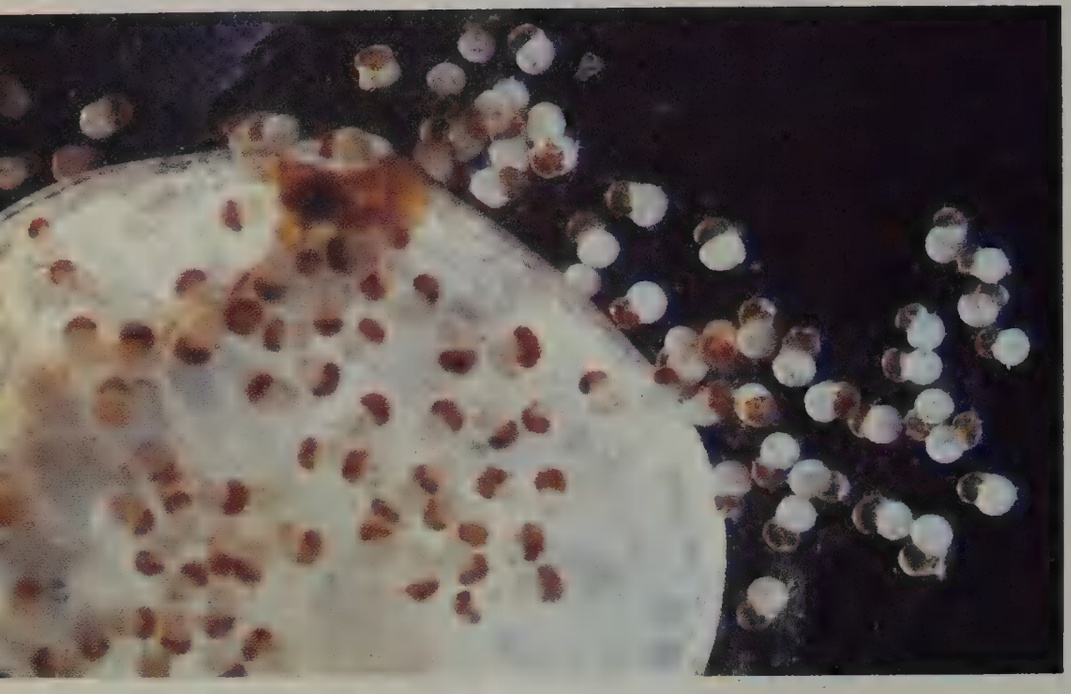


Townsend P. Dickinson

Rudolf Röttger

A larger foram may reproduce itself asexually by undergoing multiple cell divisions. Below: Hundreds of embryos have developed from the protoplasm of a single parent, and each shares some of the algae that lived symbiotically within the adult. Right: This foram has just added a row of new chamberlets on its outermost margin. The thin shell allows light to penetrate so that the algae living within may photosynthesize. The inmost chambers are darker because they have been more thoroughly colonized by algal cells.

Rudolf Röttger



the algae give some or most of that organic matter back to the host or if the host digests some of its algae, the host will again burn about 90 percent of what it gets; the nutrients in that 90 percent will go back to the algae for reuse. The nutrients can be recycled again and again, providing an indefinite amount of energy. The host–symbiont system ultimately grows by nearly the same amount of organic matter as originally contained in the food captured. That is, while an animal without algal symbionts might grow 10 grams for every 100 grams of food eaten, the animal with algal symbionts can grow nearly 100 grams for every 100 grams eaten. That is about a 10 to 1 growth advantage for the symbiont-bearer.

The scarcer the food, the greater the advantage of symbiosis. If, say, 99 percent of the animal's food must be used to live and find more food, the animal in the host–symbiont system will have nearly a 100 to 1 advantage over the animal without symbionts. Most algae cannot survive on their own when nutrients fall below a certain level. As nutrients and food become even scarcer, symbiosis becomes highly advantageous for both host and algae.

With algal symbiosis, certain organisms—larger forams, corals, and some plankton—flourish in the warm open ocean, the central Pacific, and reef environments worldwide where food is scarce and sunlight is abundant.

And why are larger foram shells so complex? Most forams build chambered shells, adding new chambers as they grow. A shell is rather like a house; the chambers are equivalent to rooms. Ceilings and floors separate the rooms from the outside, as do the outermost walls. Interior walls separate chambers. Some shells are multistoried, with interior ceilings and floors that also separate chambers. In larger foraminifera, complex interior structures include chambers divided into chamberlets; corrugated or pitted walls; and internal canal systems that run throughout the shell. These wall modifications increase the shell's inner surface area. Most of the algae are found close to the walls and ceilings, while most of the foram's own protoplasm is concentrated in the center of the chamber or chamberlet. The ceilings and floors must be thin for light to penetrate into a large shell, but additional wall structures provide added strength, especially in shells that may be an inch or two in diameter and perhaps a tenth of an inch in thickness. The internal canal systems serve as a sort of circulatory system, presumably an important asset in very large foraminifera.

Another interesting question is, of what advantage is large size? Modern larger foraminifera must live as much as a year to grow to a size of a few tenths of an inch in diameter. Very large foraminifera of ancient times must have lived for several years, perhaps as many as ten. Such longevity is particularly perplexing in simple creatures such as forams, whose primary mode of reproduction is an asexual process in which the parent simply divides its protoplasm among its offspring, ending its own life as an individual. In such cases, long life means fewer chances to reproduce. So under what environmental conditions might longer life be a greater advantage than the ability to produce offspring in a short period of time?

When a foram divides asexually, the parent cell passes along its symbiotic algae to its offspring. (Forams also repro-

duce sexually, but sexual reproduction is riskier. Each newborn must find its own algae, one of the reasons that very few sexually produced offspring survive.)

Field studies indicate that larger forams lead relatively safe lives from the time they reach a size of about a tenth of an inch in diameter until they reproduce. Most juveniles, on the other hand, perish—in two species that produce a large number of fairly small young, more than 99 percent died. One of these species lives in very shallow, wave-swept reef flats; the other is found in slightly deeper, quieter environments. Although otherwise similar, the shallow-water species lives about three times longer, grows about three times larger, and most importantly, produces about three times as many young per parent. These observations indicate, as do computer simulation models, that increased parent size can be a successful adaptation to high juvenile mortality in foraminifera.

Far and away the most intriguing question concerning forams is why lineages of larger species evolved and then died out several times in the history of the earth. The oldest group of larger forams, the fusulinaceans, evolved more than 300 million years ago in shallow lime- and shell-dominated seas at about the same time that the early amphibians and the first primitive reptiles were invading the early swamps. The fusulinaceans died out about 225 million years ago when the seas receded as the then-existing continents collided to form the ancient supercontinent of Pangaea.

About 75 million years later, Pangaea was breaking up, dinosaurs roamed the earth, and the seas again invaded low-lying parts of the continents. During the subsequent tens of millions of years, in the resultant shallow seas, several different lineages of smaller forams gave rise to larger descendants. Then, about 66 million years ago, roughly when the dinosaurs perished, most of the larger species died out abruptly for the second time. During the next 60 million years, communities of large, complex forams evolved twice—at about 55 and 30 million years ago—and died out twice—at about 35 million and 15 million years ago.

The fossil record indicates that high sea level and a warm climate were the necessary conditions for the evolution of larger forams. When sea level is high, the earth's surface becomes more evenly heated because water holds heat better than land. At those times, the marine temperature gradient between the tropics and the poles

is reduced, with sea water in polar regions as much as 25 degrees Fahrenheit warmer than during low stands of sea level.

During higher stands of sea level, vast, low-lying continental areas were covered by shallow water. Warm, nutrient-deficient seas developed gradually over millions of years, providing time and selective advantage for the evolution of long-lived, heavily armored, highly specialized algal-symbiont-bearing organisms—including reef-building corals and the larger forams.

A simple drop in sea level could have caused the elimination of the most specialized larger forams. Most of their shallow-sea habitat became dry land, and much of the remaining sea would have been made unsuitable by the sediments and nutrients in river runoff from the increasing land area. As the seas receded and high latitudes cooled, deep ocean circulation would have brought nutrients, long trapped in sluggish deep waters, up to the surface. Fast-growing algae and animals that fed on those algae would have bloomed, preventing light from reaching the underwater environment and thereby degrading the habitat for algal-symbiont-bearing marine species.

The two most recent episodes of the evolution of larger forams, one about 55 to 35 million years ago, the other about 30 to 15 million years ago, coincide with the development of high sea levels and warm climates. Each episode ended as high latitudes cooled and deep ocean circulation accelerated, apparently as a result of changes associated with the movement of continental plates.

When the larger forams proliferated, sea levels were 1,000 feet or more above present levels. Now, because deep ocean circulation is active in modern oceans, food resources, even in areas considered nutrient-deficient—such as the subtropical oceans—are probably quite rich compared with those of former times. Modern larger forams are fairly small and their shells are relatively simple compared with some of their earlier relatives.

When—at some time in the future—sea levels rise and warmer climates return to the higher latitudes, very large and complex forams may well flourish for the fifth time. □

Larger foraminifera are common in the warm, shallow waters of this Hawaiian rock pool. The characteristic golden color of some of the forams comes from diatoms (microscopic algae) living within their shells. The small, candy-striped foram in the foreground is host to a species of red algae.

Rudolf Röttger

Art Beneath the Sea

by Victor B. Scheffer

WITHIN A RAINBOWED SEA, by Christopher Newbert. *Beyond Words Publishing Co., $49.95; 208 pp., illus.*

Here are 158 exquisite photographs, printed one to a page in full color, of animals that cling to coral reefs or crawl among them or drift or swim in adjacent waters. A few pelagic species—whales, dolphins, sharks, a green turtle, and a fur seal—are also portrayed. All were photographed underwater in their native haunts in the Red Sea, the Galápagos, Cozumel, the Cayman Islands, Roatan, Belize, Hawaii, Fiji, Truk, Ponape, Palau, the Great Barrier Reef, and the Coral Sea.

Tropical reef communities display an unparalleled variety of forms, textures, and colors, partly because they are among the oldest on Earth and partly because they have evolved in regions uncommonly hospitable to life—they are the survivors of an experiment that has continued nonstop for at least a billion years in warm, sunlit laboratories. Little wonder that these communities are now populated by hundreds of thousands of species occupy-

Fill out this coupon and save the children

Complete this simple questionnaire, and befriend a needy child through Save the Children. For only fifty-two cents a day, your money, combined with that of other sponsors, can breathe new life into an impoverished village...help hardworking people in their fight for dignity...turn despair into hope for a child who has known only disaster. Fifty-two cents may not buy much where you live. But for the poorest of the poor where the need is so desperate, it can work miracles.

NH 3/5

My Name Is _____
(please print)

Address _____

City _____ State _____ Zip _____

Tell us how you want to help, by answering these questions:

1. What kind of child would you like to help?

☐ Boy ☐ Girl ☐ No preference

2. What geographical area are you interested in?

Urgent need exists in all the areas listed below, especially overseas. If you have a strong preference for a particular location, check the area of your choice. If not, won't you please let us assign a child where the need is greatest?

☐ **Certainly. Choose a child for me in an area of greatest need.**

I strongly prefer:

☐ Africa
☐ American Indian
☐ Appalachia (U.S.)
☐ Bangladesh
☐ Chicano (U.S.)
☐ Colombia
☐ Dominican Republic
☐ Gaza Strip
☐ Honduras
☐ Indonesia
☐ Inner Cities (U.S.)
☐ Israel
☐ Lebanon
☐ Mexico
☐ Nepal
☐ Philippines
☐ Southern States (U.S.)
☐ Sri Lanka
☐ Thailand

3. Would you like a picture of your sponsored child?

Shortly after we select a child for you, we can send you a photograph and brief personal history, if you desire.

☐ Yes ☐ No

4. Would you like to exchange correspondence?

If desired, correspondence can build a meaningful one-to-one relationship and provide a unique educational experience for the sponsored child. In areas where illiteracy is high, a village representative will keep you informed of the progress your child is making. Translations, where necessary, are supplied by Save the Children.

☐ Yes ☐ No

5. Would you like information about the child's community?

When you become a sponsor, your funds are used to help children in the most effective way possible—by helping the entire community with projects and services. For health care, education, food production, and nutrition. Several times a year you can receive detailed reports on these community activities which provide permanent improvements to the child's environment. Would you like to receive such information?

☐ Yes ☐ No

6. How do you wish to send your sponsorship contribution?

Enclosed is my check for $_____.

☐ Monthly, $16
☐ Quarterly, $48
☐ Semi-annually, $96
☐ Annually, $192

7. Do you wish verification of Save the Children credentials?

Save the Children is indeed proud of the handling of its funds. Based on last year's audit, an exceptionally large percentage of each dollar spent was used for program services and direct aid to children and their communities. Due to volunteered labor and materials, your donation provides your sponsored child with benefits worth many times your total gift. Would you like to receive an informative Annual Report (including a summary financial statement)?

☐ Yes ☐ No

(A complete audit statement is available upon request.)

8. Would you rather make a contribution than become a sponsor of an individual child at this time?

☐ Yes, enclosed is my contribution of $_____.

☐ Check here for general information about our unique programs for aiding impoverished children.

Insects and Flowers
The Biology of a Partnership

Friedrich G. Barth
Translated by M.A. Biederman-Thorson

"This lively book brings a great deal of new information into clear focus. It will be welcomed by both laymen and students."
—*Peter Raven, Director of the Missouri Botanical Garden*

A volume that will be a perfect gift for gardeners, natural history enthusiasts, and students of botany and zoology, *Insects and Flowers,* with a charming text and vivid photographs and illustrations, reveals how the colors, shapes and scents of flowers ensure pollination in ingenious and sometimes fantastic ways. $35.00

296 pages. 47 color photographs. 16 halftones.

Clownfish in sea anemone

ing countless ecological niches. The author puts it this way:

The reef is a marvelous compression of life, a proving ground for genetic design. The intense competition for food and space by members of this community is fuel for the engine of evolution. On the reef we have a special opportunity for intimate contact with the inner workings of this endless, intriguing process.

The book is designed to be "a visual poem, photographs and words celebrating not just the intricate fabric of life which evolution has woven into the sea, but the origin and life force common to all things." I suggest, however, that the product is more a guide to artistic inspiration in nature than a species chart of Darwinian adaptation. Its photographs are clean and sharp; they have an arresting, posterlike quality. Newbert often zooms in to frame a single crab larva, the eye of a fish, the tentacles of a sea anemone, or the siphon pore of a tridacna clam. (He's fond of tridacna clams; he gives us eight views of their parts.) As a result of his absorption with what may be called architectural detail, his work stands apart from that of many or most undersea photographers who aim to show us the whole animal.

Some reef organisms display their charms openly. They are "found art" and present no photographic challenge. Others hide their beauty until someone like Newbert comes along and reveals it through expert attention to lighting, scale, angle of view, and background.

Several of the photographs in the book will startle zoologists. Five pilot whales pass in review beneath the surface, their slick bodies aligned in military precision. A dense-beaked whale and a melon-headed whale approach the camera—the first of their kind, I believe, to have been photographed underwater in the wild. A flying fish soars on silver wings outspread against a black sky . . . in fact, it is swimming deep in the Pacific off Hawaii's Kona coast at night.

The book's brief text is scattered among the photographs. For the most part it explains how Newbert feels when he moves quietly through a sun-dappled sea or dives at night when the reef creatures that habitually hide during the day may expose their unexpected charms. On such occasions, the brief flash of a strobe lamp is the first full spectrum of light that the creature has seen or will ever see. Newbert recalls one of the many times when he simply flowed with the current, studying the life around him.

Winding, twisting, stretching out, then reforming, they moved in perfect synchronization. Thousands of tiny fish, none ever missing a beat. Sunlight streaming through the water flashed silver as they turned in unison, a single being, a single spirit. I was mesmerized by their rhythm. How did they know when to turn? And where? By what mysterious signal did their rhythm change? A beat goes on underwater and there have been those moments when the beat and I merged.

Yet I wonder a little about this book, as I have wondered about others in which graphic art and prose were combined. Would not either expression by itself have been more convincing, more eloquent? Quite apart from the accompanying words, Newbert's images of undersea life seem to me as complete as one could wish. Witness the goatfish eye in burning reds and black, which can be seen as a vision by Robert Blake. Crinoid arms are bursting fireworks. A clownfish peering from the pulpy fingers of an anemone is a cartoon without words. Maxfield Parrish, in his most exalted moments, could never have painted the blues and oranges of Newbert's soft coral tree. Poised in watery space, a Spanish dancer nudibranch and a pair of fire gobies hold for applause. Other

Vanguard adds an insured municipal bond portfolio.

THE FIRST COMMISSION-FREE WAY TO INVEST IN INSURED MUNICIPAL BONDS.

Now you don't need to pay a sales commission to get the safety and high yields of insured municipal bonds. Because Vanguard has added the Insured Long-Term Portfolio—a tax-free bond fund that's both insured and no-load.

The Portfolio invests in insured long-term municipal bonds. Such bonds are rated AAA. So there's potential for high tax-free* yields *plus* a guarantee of timely payment of principal and interest. The insurance coverage does not protect the share price against normal market fluctuations caused by changes in long-term interest rates.

Vanguard Insured Long-Term Portfolio offers:

- Unlimited free checkwriting for $250 or more.
- Option to reinvest monthly dividends for tax-free compounding.
- Toll-free exchange and redemption.
- Minimum initial investment of $3,000.

*Income is 100% free from Federal income tax but may be subject to state and local taxes.

Arrow crab

scenes are jungles on undiscovered planets, sensual forbidden fruits, gatherings of amoeboids, the frosts of new chemicals, or strange and wondrous things in an inventor's shop. All these images are landscapes of the mind. They deserve careful study by designers, sculptors, choreographers, and others who find inspiration for their art in the outdoor world.

Newbert, formerly a *National Geographic* staff photographer, lives on the island of Hawaii and is the author of two best sellers, *The Australians* and *The Hawaiians*. The design of his latest book is a tribute to the author's "fierce commitment to quality." Each photograph is printed in glossy inks on white stock. The surrounding page is beige, with a matte surface. Thus any white parts of the original photograph are saved, while the viewer is spared the distraction of a white frame.

And there's a promotion appeal. Each copy of the book (which can only be purchased at Walden Bookstores across the country) contains a coupon promising that a tree will be planted, in the name of the buyer, on Hawaii's Molokai Island.

This is a fine book. One can only wish Chris Newbert happy hunting when again he ventures into Shelley's realm of "The sea blooms and the oozy woods which wear / The sapless foliage of the ocean."

Victor B. Scheffer is a naturalist and author retired from federal wildlife service. His most recent book is Spires of Form: Glimpses of Evolution.

Your first step toward amassing a fortune in real estate: mail the coupon below.

Return the attached coupon for your first 2 FREE lessons in a remarkable wealth-building program.

Since the gilded age of land barons, real estate has been the foundation of some of the greatest fortunes ever amassed in the United States.

Today, real estate continues to hold incredible wealth-building opportunities virtually anyone can use. But to grow rich in today's complex market, you need more in-depth knowledge than any real estate book or seminar can offer.

That's why Hume Financial Education Services created a unique self-study program called *Successful Real Estate Investing.* In a clear step-by-step format, it provides you with a comprehensive grasp of all aspects of real estate...the profitable techniques, professional advice and proven formulas that allow you to invest wisely and successfully.

Can you still make a "killing" in today's market?

Your prospects for making big money in real estate are as good now as ever. Consider today's climate:

Housing demand is at an all-time high, but supply is not keeping up—creating an attractive investment opportunity.

You can begin with little money, and use borrowed money to multiply your potential profits.

- Real estate is resuming its historic upward trend. After a recent recession, housing sales are steadily rising.

Successful Real Estate Investing alerts you to the ways you can capitalize on today's and tomorrow's opportunities. Ways you can benefit from the new income property tax laws...a form of real estate you can buy and sell as quickly as stocks...how to take advantage of depreciation...all the avenues that can realistically lead you to impressive wealth.

Profit strategies you can use right away.

No other source we know of offers you the scope and detail of *Successful Real Estate Investing* in such an easy-to-understand format. You'll learn a wide range of investment strategies that will help you develop a profitable investment program based on your own needs and goals.

For example, you'll discover:

- How to use leverage to multiply your profit potential
- Why now is such an ideal time to invest in apartments
- 60 factors that boost a location's profitability
- How to find special low-interest mortgages
- How to invest with nothing down

You can put this information into profitable action immediately. What's more, you can learn it in your own home, at your own pace. Each lesson is easy to understand, so you'll be able to invest with complete confidence.

You don't need a bundle to make a bundle.

It doesn't matter how much money you have to invest. The program shows you how to profit regardless of your current cash situation...and regardless of whether or not you've had any prior real estate experience.

You take no risk. Your satisfaction is guaranteed.

Prove the program's value to yourself by returning the coupon below, along with your refundable $5 registration fee. We'll send you the first 2 lessons—and a Comprehensive Guide to Real Estate Terms—free.

Soon thereafter, you'll receive lessons 3 and 4. If, after 15 days, you decide you don't want to continue the program, just send lessons 3 and 4 back. We'll pay for the return postage and promptly refund your $5 registration fee.

To go ahead with the course—and continue discovering how to build your real estate fortune—simply pay for lessons 3 and 4. You'll receive 2 lessons every 3 weeks at $10 per lesson, plus a small charge for shipping and handling. You'll always have 15 days to evaluate each lesson, and you may cancel at any time.

Whatever you decide, lessons 1 and 2 and the Guide to Real Estate Terms are yours to keep—free.

As you see, there's no risk to you. In fact, if you're serious about amassing a fortune in real estate, your prospects have never been better...with *Successful Real Estate Investing.* So take that simple first step. Mail the coupon for your 2 free lessons and free guide today.

Tough Nuts

Despite some superficial similarities, Brazil nuts and macadamia nuts present a study in contrasts

by Raymond Sokolov

The macadamia and the Brazil nut are not related in any way except one. They are very hard to crack. I was once given a bag of unshelled spherical macadamias that defied nutcrackers and hammers and only surrendered their edible kernels when I pounded them between two large rocks.

In Hawaii, where the largest commercial macadamia plantings grow, nut stores recommend screw-type nutcrackers fitted with small cups to keep the macadamias from escaping as pressure is applied. Some people drive cars over them. But most consumers buy mechanically prehulled macadamias at a fabulous price—$10 a pound approximately—caused by high Hawaiian costs and the multiple harvesting necessitated by the macadamia's impractical habit of not bringing all of its fruit to maturity at the same time.

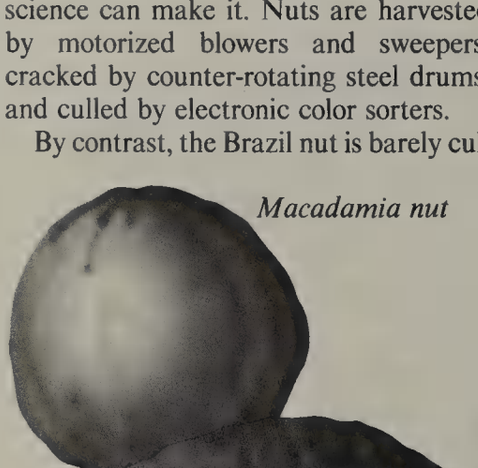
Macadamia integrifolia is, nevertheless, a "modern" plant, intensely cultivated, hybridized, and grafted. This is all very recent. In fact, the first cultivar is still producing nuts in Queensland, Australia, where a Brisbane botanist named Walter Hill planted it, from seed cracked in a vise, in 1858.

Hill had discovered this evergreen of the Proteaceae family the year before on an expedition with that patriarch of Australian botany Ferdinand von Mueller. As Frederic Rosengarten recounts the story in *The Book of Edible Nuts* (Walker and Co.), Mueller named the "new" tree after his friend John Macadam, a Scottish physician who was secretary of the Philosophical Institute of Victoria. By legend, Macadam never tasted a macadamia. Before he was able to sample the nut that would make him immortal, Macadam died aboard ship on the Tasman Sea, heading for New Zealand. He had cracked his ribs in rough weather, contracted pleurisy, and never recovered.

We also know the name of the man who first brought the macadamia to the big island of Hawaii, where it flourishes today as nowhere else and, as we munch, is replacing the traditional Hawaiian crops of sugar and pineapple on thousands of acres of land. The Johnny Appleseed of the macadamia was William Herbert Purvis, a prophetic soul who gathered seeds near Mount Bauple in Queensland, Australia, and put in seedlings at Kukuihaele, Hawaii, about 1882. One of the trees he planted is alive and still fecund as it enters its second century.

Today's macadamia industry is as mechanized and up-to-date as money and science can make it. Nuts are harvested by motorized blowers and sweepers, cracked by counter-rotating steel drums, and culled by electronic color sorters.

By contrast, the Brazil nut is barely cultivated at all, even after several centuries of international export trade in this economically valuable wild fruit. A modern excavation in Alexandria, Virginia, unearthed Brazil nut shells dropped there 200 years ago.



Macadamia nut

Brazil nut

Today, Brazil is still, in the words of Charley's Aunt, "where the nuts come from." Indeed, they continue to come mostly from the northern state of Para, where they grow wild in the Amazon jungle and are harvested by hand, as they always were, after they have fallen from the 100-foot high branches of *Bertholletia excelsa*.

Recent observers have not hesitated to compare the life of the *castanheiros* who gather these nuts to slavery. The work itself is miserable and hazardous. *Castanheiros* trek through the jungle barefoot on narrow trails. In the rainy season, they live in forest lean-tos for six months at a time, not knowing what their pay will be and steadily incurring debts for their subsistence at the company store.

What we call Brazil nuts grow in clusters of twelve to twenty-four, inside woody pods known as *ouricos* (or sea urchins) from their barbed outer shell. They weigh four pounds and when they plummet from on high, occasionally kill people.

In recent years, the export of these laboriously gathered nuts to their principal market, the United States, has brought Brazil millions of dollars in trade. This substantial commerce is now threatened, according to a recent Associated Press dispatch, by a jungle war over land rights. Twenty people were killed between the beginning of 1983 and fall of 1984. Plantation owners blame gangs of thieves who, they say, murder nut pickers and abscond with nuts and valuable wood. Local activ-

Matter of Taste

ts and priests claim the thieves are really e hired guns (*pistoleiros*) of the big ndowners, who pay them to terrorize nall farmers who grow their own food on nd the plantation owners claim is theirs. ve hundred settlers' homes have been urned. And the Brazil nut crop has re-ortedly fallen by 40 percent.

From the fragmentary and discordant vidence in this dispatch, it is not possible determine how this strife in the back ountry of the Amazon will ultimately af-ct the economic future of Brazil nuts. lanned cultivation and hybridization of ees is still in its infancy. The supply of ild nuts is very great. Labor has been ery cheap. And the long maturation pe-od of naturally occurring trees is twelve fifteen years, long enough to discourage ctive planting. One explanation for the urrent Brazil nut wars is that plantation wners have hired the *pistoleiros* to cut own their own trees so as to clear land, il-gally, for cattle raising. (Cheap land oncessions are available from the state nly for nut production.) These attacks on easants and primordial trees may be part f the general program of development nd deforestation of the Amazon.

Countless plants and animals are nreatened, not to mention indigenous hu-nan beings and their way of life. The tow-ring umbrellas of *B. excelsa* are particu-rly easy targets. Their nuts have been roduced and marketed in such a primi-ve manner that they can't really compete ith "modern" nuts that are sold shelled nd roasted. In the Amazon, cow meat is a etter bet per acre than nut meat.

In its own ecological niche, the Brazil ut tree has, however, found at least one consumer" group capable of dealing with s hard and tenacious hull. I'm thinking of

certain fish in the Amazon that, according to the American-born researcher Michael Goulding, have evolved large molars and jaw muscles so that they can live off Brazil nuts that drop into their territory.

Human consumers are not so well provided for the challenge of the Brazil nut's flat-paneled brown shell. Even people strong enough to crack those shells with a conventional nutcracker discover more often than not that they usually cannot extract the white flesh from the shell without major efforts that risk pulverizing the flesh and lacerating the thumbs against the sharp corners of the cracked shell. This is the main reason that people leave Brazil nuts for last in a bowl of mixed, unhulled nuts. Another reason is that Brazil nuts cracked from the shell have a boring, starchy taste because they haven't been roasted.

This wrong-headed system of marketing is probably the result of history and poverty. Brazil has only recently acquired the packing technology necessary for the safe processing of Brazil nuts in tropical weather. I have been unable to find out if there are plans not only to shell but also to roast the nuts. Apparently, shippers are content to keep on sending dehydrated but raw nuts north, as they have for 200 years. But I am sure they would sell many more nuts if they roasted them.

Roasted Brazil nuts are delicious, far superior to raw nuts, just as roasted peanuts are superior to raw peanuts. You can test this proposition for yourself. Just a few minutes in the oven solve all the problems of the Brazil nut. The shells pop away from the flesh, leaving most nuts whole. And the flesh, turned an appealing brown right through, has improved immeasurably in taste (see recipe).

This process could, of course, be easily done on a commercial basis, if not in Brazil, then at the conventional port of entry for unshelled Brazil nuts at Mobile, Alabama. (The method generally used for Brazil nuts packed in cans of mixed nuts is gentler and does not bring out the flavor as well as roasting in the shell.) Perhaps some people are already doing this, but they must be operating in relative secrecy. For the most part, the historic Brazil nut industry is still sunk in its bad old ways, while the upstart macadamia growers have benefited from advanced science and merchandising right from the start. They are even enjoying a special boomlet now, during this period of excitement over all-American ingredients for so-called American *nouvelle cuisine*. I suppose it isn't so terrible if customers are made to think that macadamias are native American nuts, when they're Australasian. I like fish sautéed with macadamia dust as much as the next fellow. Ditto for macadamia ice cream. But I do think that it's time to put in a good word for a nut with a much longer history in this country, a nut that really does come from this hemisphere, that is cheap and at least as interesting in taste as a macadamia—after it's roasted.

Raymond Sokolov is a writer whose special interest is the history and preparation of food.

Brazil Nut Brittle

3 cups sugar
1 cup light corn syrup
2 cups roughly chopped, roasted Brazil nuts (see note)
4 teaspoons baking soda
1½ tablespoons butter
1½ teaspoons vanilla

1. Stir together the sugar and syrup with ½ cup water over high heat in a 6-quart saucepan. Continue cooking, without stirring, until the mixture reaches 240 degrees on a candy thermometer. The sugar undergoes various changes in its crystal structure as its temperature is raised. Some changes take longer than others. Do not give up when the mixture seems determined not to heat up further after it reaches the boiling point. When it does attain 240 degrees, the mixture is at the "soft ball" stage, so called because cooks without thermometers learned that at this temperature (identified with exactitude only later), sugar mixtures would make a soft ball when immersed in cold water.
2. Add the Brazil nut fragments and continue cooking until the mixture reaches the "hard crack" stage, 300 degrees on the thermometer. Obviously, if you dropped some of the mixture into cold water at this point, it would turn brittle and glassy, hard and easy to crack.
3. Remove from heat and stir in the baking soda, butter, and vanilla. The mixture will bubble up dramatically at this point. This is why a large saucepan is recommended.
4. As soon as the baking soda has been smoothly incorporated, pour the brittle onto a greased marble surface or a large, greased jelly roll pan (or any metal pan with sides so that the brittle doesn't creep off the greased surface). Cool and then break into pieces. Store in a tin.

Yield: Two pounds

Note: Start with three pounds of unshelled Brazil nuts. Roast them on a baking sheet in a preheated 400-degree oven. After 15 minutes, test a nut with a nutcracker or pliers. It should crack with relative ease, and the nut should emerge whole or in two large pieces, nicely browned. If this does not happen, continue roasting a few more minutes. Crack nuts immediately after roasting. You will probably get more than you need for the recipe this way, but it is difficult to predict in advance what the yield in nutmeats per pound of unshelled nuts will be.

Macadamia Nut Brittle

Adapted from *The Simple Art of Perfect Baking*, by Flo Braker (William Morrow and Co.)

Oil
3 ounces unsalted macadamia nuts (see note)
¼ teaspoon baking soda
½ cup (100 grams) granulated sugar
1 ounce (2 tablespoons) unsalted butter

1. Using a paper towel, spread a thin film of unflavored vegetable oil on a baking sheet; set aside.
2. Pour the nuts into a food processor fitted with a steel blade and process with off/on bursts until they are coarsely chopped. You should end up with ¾ cup. (It is also possible to chop the nuts with a chef's knife on a cutting board.) Pour into a small bowl, sprinkle with the baking soda, and toss briefly just to combine.
3. Pour ¼ cup (2 ounces) water, then the sugar, into a 5-cup copper sugar pot or a 1-quart, heavy-bottomed saucepan, and place over low heat. Swirl to moisten the sugar. Heat until the sugar dissolves. Add the butter, raise heat to medium, and boil the mixture until it registers 280 degrees on the candy thermometer.
4. Remove from heat, immediately add nuts, and stir briefly just to combine. The mixture will foam because the heat activates the soda, which lightens the brittle's texture. (Too much stirring will deflate the brittle.) Pour the mixture onto the baking sheet. Set aside to cool and harden. When the brittle is completely cool, store it in an airtight metal container for up to 1 month at room temperature.

Note: Unsalted macadamias may be found at health food stores. If only salted nuts are available, toss and roll them first in a dry towel, then in a damp towel. Spread them in a thin layer on a baking sheet to air dry for a few hours. Cashews may be substituted for macadamias.

EARTH, SPACE, STARS
ARTIFICIAL INTELLIGENCE, ROBOTICS
LIFE, MIND, BODY, THE ARTS

OMNI Magazine invites you to embark on an extraordinary voyage—travel the lands and seas of Earth, venture to the far reaches of space and the stars, into the complexities of artificial intelligence, beyond the genesis of robotics, through the wonders of life, into the enigma of the mind and the wonders of the body. Every month OMNI Magazine presents art at its finest, science fiction at its very best, interviews with today's leading thinkers and games that will challenge the brain. AIRLINES OF HONDURAS

Hercules Glade, Missour

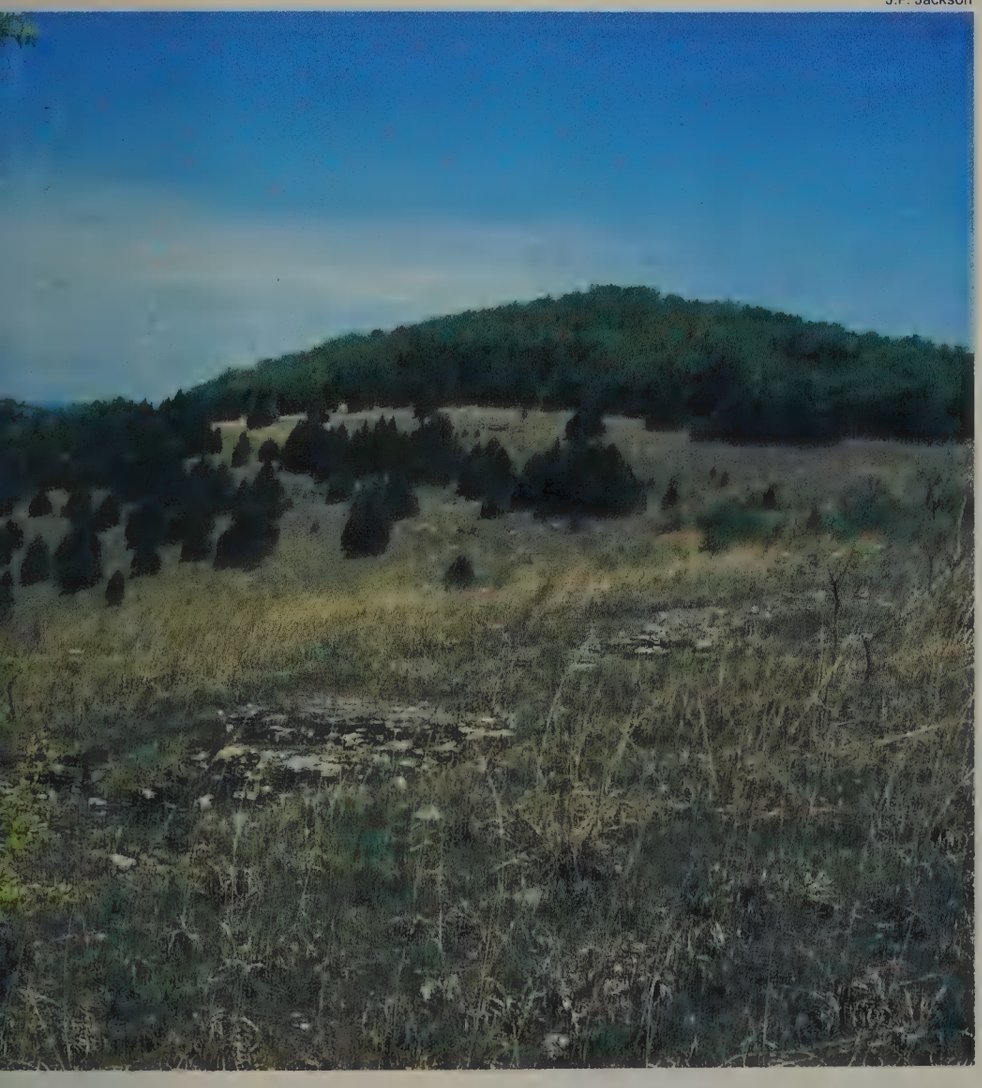
by Robert H. Mohlenbrock

Some people call them balds or knobs, while others refer to them as barrens. I prefer glade, which I define as a forest opening strewn with exposed rocks. There are hundreds of glades in the Missouri Ozarks, ranging in size from a few hundred square feet to several hundred acres. Although most glades are surrounded by dense, oak-dominated forests, there is little encroachment by the trees. For one thing, the soil in the glades is not nearly deep enough for oaks. For another, most glades face south and west, and the hot summer sun strikes them directly, creating an arid and generally inhospitable habitat. Not even summer thundershowers moisten the ground; the water runs rapidly off the shallow soil.

A few trees do grow where pockets of soil have accumulated in the glades. Red cedar is common, being able to survive the dry conditions because of its diminutive, needlelike leaves, which lose little moisture through evaporation. Less usual are two small trees whose roots deeply penetrate the cracks in the rocky substrate to reach the limited supply of water: the smoke tree, with its blue-gray fruiting sprays, and the fringe tree, with its pendulous clusters of white flowers.

To thrive in the glade environment, plants must compensate for the lack of moisture between June and September. Annuals complete their life cycle in a short time, then rely on their seeds for their perpetuation the following year. Most do not take the trouble to survive the summer. The dwarf leavenworthia mustard, for example, germinates in late autumn, overwinters with a tiny cluster of leaves, flowers in late March, forms its seeds by early May, and then dies back before the heat of the summer. The slender-leaved heliotrope, on the other hand, usu ally germinates in June, flowers in July and August, and forms its seeds in Sep tember. While this may seem like a poo strategy, the plant thus takes advantage o a niche left by the annuals more typical o the glades. As a compensation, this helio trope's very narrow leaves control wate loss. With the rising temperatures of sum mer, the edges of the narrow leaves roll un

J.P. Jackson



and inward, exposing even less area to sun's rays.

Perennials have to survive the entire owing season to build up enough food reves, mostly starches, to last the winter d produce new leaves the next spring. nnuals generally require fewer reserves form their seeds.) To cope with midmmer conditions, flower-of-an-hour and se aloe have thick fleshy leaves for storing large quantities of water. Prickly pear cactus retains excess water in fleshy, padlike stems; there is no water loss from its leaves, which are modified into spines. The leaves of wild petunia are covered with a dense entanglement of hairs, a barrier against rapid evaporation of water. The food reserves of the Missouri black-eyed Susan accumulate in thickened stems just beneath the surface of the soil,

50% OFF NORMAL RETAIL

100% Merino Wool Mattress Pad

MANUFACTURER DIRECT

A tradition in Europe is sweeping America. Soft 100% Merino Wool cushions and cradles your body for a deeper, more restful night's sleep. Even the best mattress creates pressure points on the shoulders, hips and back. Soft, thick Merino Wool conforms to the contours of your body, relieving pressure points. Many people report they fall asleep faster, enjoy a more restful sleep and wake up feeling completely refreshed.

Wool is a natural insulator. In winter the pad retains body heat to keep you warm. In the summer, the pad keeps you cool by absorbing moisture.

The Wool Bureau has given this product the Superwash® designation. It can be machine washed and retain its original softness, resiliency and durability.

We use Merino Wool, absolutely the finest wool money can buy. Finally, we manufacture the pad ourselves and sell it directly to you, eliminating the middleman and retail markup and eliminating half the cost.

If you don't enjoy the best night's sleep you've ever had, simply return it to us for a complete refund. Delivery: Immediate.

where they are protected from the sun, while the nodding wild onion and purple oxalis produce underground bulbs.

In the Ozarks, glades are distinguished by rock type, and rock type affects the vegetation. Centered in southern Missouri and northern Arkansas, these mountains constitute one of the oldest exposed geological regions in the world. A billion years ago, a thick lava flow covered the area. After it had cooled, a great mass of molten rock thrust upward, melting and absorbing some of the lava in its way. The molten rock cooled very slowly, forming a coarse-grained granite. After eons of erosion, this granite dome eventually sank beneath the sea and was covered by several thousand feet of sedimentary limestone and sandstone. Two subsequent movements, one 400 million years ago and another more recently, again raised the region's rock mass. Since then, erosive forces have continued their work. In places, the limestone and sandstone have been worn away, leaving the ancient granite exposed; elsewhere, sandstone or limestone dominates.

Perhaps the most pristine of all the glades is Hercules Glade in southwestern Missouri. It lies in a 12,000-acre wilderness of the same name administered by the Mark Twain National Forest. Hercules is a limestone glade; what little soil it has averages only about four inches deep.

During winter and early spring, the glade is uncharacteristically wet, ofte with shallow pools of standing water, b cause of abundant rain and snow. There less evaporation because of the higher hu midity. May brings a combination of giar purple-flowered beard-tongue (penste mon), whose tubular flowers measur more than two inches long and are nearl as broad; blue false indigo, with densel packed elongated clusters of flowers; an Missouri evening primrose, whose brigh yellow, saucer-sized flowers conceal th rest of the plant.

In summer, lack of rain, rapid drainage and maximum evaporation create des ertlike conditions in the glade. Plants tha persist into summer often wilt, and an mals either burrow into the shallow soil o retreat into the surrounding forest. Ther is a lull in the blooming of wildflowers while dense stands of tall grasses give Her cules Glade the look of a prairie. Big an little bluestem, prairie dropseed, India grass, and side-oats grama, all characteris tic plants of the prairies of Kansas and Ne braska, dominate the scene. Seeds of thes grasses, which probably arrive by way o the frequent, strong westerly winds, hav a good chance of germinating in the ab sence of competition from shade-formin trees. In late August and September, th glade again becomes a sea of color—or ange Missouri black-eyed Susans, cylin drical violet spikes of blazing stars, an

owded purple heads of the daisylike
lafoxia.

Although the plant life is the star at-
action of Hercules Glade, the animal life
also intriguing because of its western af-
nities. The scissor-tailed flycatcher can
e seen on occasion, an attractive bird that
not uncommon in Oklahoma but just
rely gets into Missouri. The gawky
adrunner, better known from Arizona,
pparently arrived in southwestern Mis-
uri about 1956, spread to many glades,
d then started to decline after the rigor-
s winter of 1976–77. Another western
imal that sometimes races at high speed
er the rocky terrain is the collared liz-
d, a pugnacious, foot-long reptile readily
entified by the two black bands around
neck. Huge, hairy-legged tarantulas oc-
sionally crawl over the stony surface,
hile underneath some of the rocks lurks a
ecies of scorpion.

The Morning Sky Gets Better and Better

by Thomas D. Nicholson

During early March, Venus, still brilliant and well placed in the evening sky, is joined by Mercury in a favorable elongation. Any evening that you can see Venus, from the 10th to the 20th, look below it and to the left. If you see another star, it can only be Mercury. After Venus begins its retrograde motion on the 12th, however, it rapidly loses the advantage of its height above the horizon. Mercury, unfortunately, dims swiftly after the 10th. Both will be gone from the evening sky by late March.

The planetary scene, so much a part of the evening sky this past autumn and winter, now shifts noticeably to the morning. Saturn and Jupiter are already there, the latter brighter and easily seen in the southeast at dawn all month. Saturn rises before midnight and looks ever so much like a twin star to Scorpio's Antares during the early morning hours. The moon helps you find them on the morning of the 12th. Venus's swift disappearance in the evening presages its equally swift appearance to the sun's right, where it will become an excellent morning star by late spring.

The following events occur at local times unless otherwise indicated.

March 1: The moon is only one day past first quarter at the beginning of March, visible in Gemini until it sets after midnight. The two bright stars to its left are Pollux and Castor, while Aldebaran, in Taurus, is to its right and below.

March 2–3: The fattening gibbous moon moves out of Gemini and into Cancer, passing from right to left below Gemini's "twin" stars, Pollux and Castor.

March 5: The crescent moon is in Leo, about where the Lion's heart should be. The star below it is Regulus, Leo's brightest, and the circle of stars above Regulus forms the Lion's head. A triangle of stars to the left marks the Lion's haunch and tail, with the star Denebola at the end of the tail.

March 6: Full moon occurs at 9:13 P.M., EST, in Leo.

March 7: Saturn, now up by midnight, is stationary relative to the stars and begins to move westward (retrograde). It has been drifting to the east through Libra, but it won't make it into Scorpius until late in the year. For the next two months, Saturn moves away from Scorpius, back into Libra.

March 8: Perigee moon (nearest the earth) is in Virgo, near its brightest star, Spica.

March 11–12: The gibbous moon rises close to Saturn about midnight and moves up the sky with it on the morning of the 12th. Both are high in the south before dawn. The reddish star below the moon is Antares, in Scorpius.

March 12: Venus is standing still against the background of stars just before it begins to come between the earth and the sun. Now its westerly (retrograde) motion takes it quickly toward the sun and out of the evening sky.

March 13–14: Last-quarter moon is at 12:34 P.M., EST, on the 13th. On the morning of the 14th, the rising moon is in Sagittarius, with the stars of the "teapot" below it.

March 17: Jupiter is the bright object near the rising crescent moon this morning. Both are in Capricornus. The moon passed from right to left below Jupiter at about 9:00 P.M., EST, on the 16th. Mercury reaches its greatest separation to the left of the sun today (greatest easterly elongation), its best position this season as

Presenting in an Exclusive Limited Edition

"The American Buffalo"

A stunning original work in the rich tradition of classic bronze sculpture.

SHOWN SMALLER THAN ACTUAL SIZE OF 6⅛" HIGH.

- **Meticulously and vividly detailed with astonishing naturalism.**
- **Hand-finished and hand-rubbed to the rich luster of the finest bronze sculptures.**
- **Hallmarked, registered and individually serially numbered. Certificate of Registration.**
- **Edition limited to only 9500 serially numbered sculptures.**

Thundering across the vast Western plains in tremendous herds, the American buffalo was once as part and parcel of the Old West as the endless sky, the jagged mountains, or the Indian tribes. Today, saved from extinction, this magnificent beast is once again a powerful symbol of America.

And now, for the first time ever, in a special tribute to the buffalo, the New England Collectors Society is proud to announce the issue of "The American Buffalo" in a strictly Limited Edition of only 9500 individually serially numbered sculptures.

The dramatic and life-like work is painstakingly created of cold-cast bronze, a sculptor's mix of powdered bronze and resins that holds even finer detail than traditionally hot-cast bronze. Individually cast, then hand-finished and hand-rubbed to a lustrous patina, "The American Buffalo" is a compelling original work.

Each serially numbered sculpture will be hallmarked, registered, and accompanied by a Certificate of Registration. Priced at only $125.00 each, "The American Buffalo" is a remarkable value in great Western Art.

To acquire this exciting work simply return the accompanying reservation application. You need send no money now.

"The American Buffalo" U 22

Limit: one per person

NE New England Collectors Society
237 Saw Mill Road, P.O. Box 464
West Haven, Conn. 06516

Please accept my reservation for "The American Buffalo", to be crafted for me in cold-cast bronze at $125.00 plus $3.00 for shipping and handling.

I understand I need send no money now. When my sculpture is ready for shipment, I will be billed for my deposit of $32.00* and, after shipment, for the balance in three monthly installments of $32.00* each.

I would like my four equal payments of $32.00* charged to my:
☐ MasterCard ☐ VISA ☐ American Express

an evening star. March evening elongations are favorable, so the opportunity of seeing Mercury low in the west after sundown should be good, even though its brightness is now diminishing.

March 19: This is the last morning to see the late crescent moon in the dawn sky before it becomes new in a few days.

March 20: The sun arrives at the vernal equinox (where it crosses the equator from south to north) at 11:14 A.M., EST, and spring begins in the Northern Hemisphere. The sunrise-sunset tables identify March 17 as the date on which day and night are of equal length in the mid-northerly latitudes. Refraction by the atmosphere explains most of the difference.

March 21: New moon is at 6:59 A.M., EST, in Pisces, very close to the vernal equinox.

March 22: At sundown tonight, you may have a chance of seeing the very slender crescent moon. Although it is only about a day and a half old, it is steeply up the sky relative to the sun. Should the western sky be clear enough to see the moon, look to its right for Venus, a bit higher, and Mercury, dimmer than Venus and about halfway between that planet and the moon. Both planets were in conjunction with the moon earlier today and with one another at about 9:00 P.M., EST.

March 23: Apogee moon (farthest from the earth).

March 23–24: The crescent moon i easily visible these nights, close to Mars which is about as bright as Hamal, in Ar ies above them. Mercury begins its retro grade motion on the 24th.

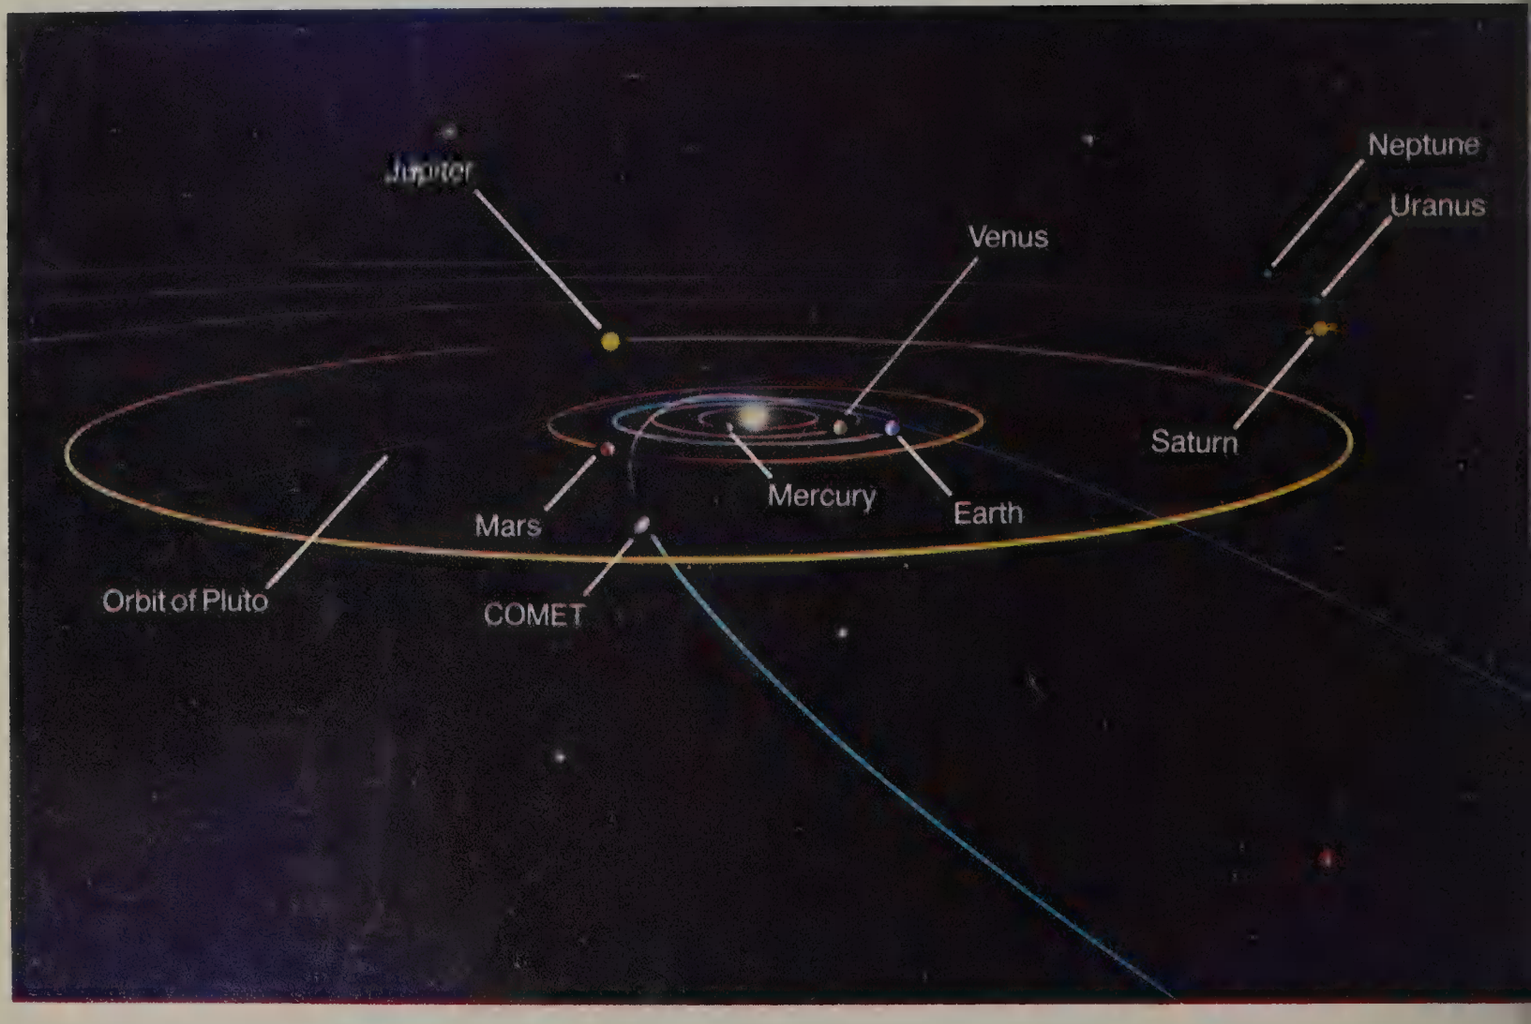
March 26–30: The waxing moon move past the bright stars of Taurus and Gem ini. First-quarter phase is at 11:11 A.M. EST, on the 29th.

March 31: The moon is in Cancer, mid way between Gemini's two bright stars Pollux and Castor, and Leo's Regulus.

Editor's Note: The Sky Map in the Janu ary issue shows the evening constellation and stars for this month and gives the dates and times for use.

Halley's Comeback

Helmut Wimme



This month, our view of Halley's comet is oriented as it was in February, from beneath the plane of the planets, looking up at them. But we have focused in closer to the inner planets, to illustrate in greater detail the comet's path as it approaches them. On this scale, we can show more clearly the movement of the comet for several more months. The illustration shows the location of the planets—from Jupiter inward to Mercury—in their orbits, with the comet's orbit tilted up toward them. The position of Halley's comet is again represented by a small cometlike image on its elongated orbit, even though no visible structure has yet developed. Still well south of the solar system's main reference plane (the ecliptic), the comet is moving steadily northward toward the ecliptic as it moves closer to the sun. It is now closer to the sun and to the earth than is Jupiter's orbit, but is still fa away from the inner region of the sun's realm, where the four ter restrial (earthlike) planets—Mars, Earth, Venus, and Mer cury—cluster together. During March, Halley's comet move 28 million miles closer to the sun, accelerating slowly as it ap proaches perihelion (the point nearest the sun). On March 9 when it is eleven months away from perihelion passage aroun the sun, the comet will have moved in to about 430 million mile from the sun. In that part of the sky visible from the earth, th comet is located in the constellation Taurus, still well above ou western horizon during March evenings. But it remains far to dim for us to see. Later in the year, when chances of seeing it ar better, "Celestial Events" will locate it in greater detail.

NATURAL HISTORY Members' Market

ATURAL HISTORY Magazine offers members a free service. Certain advertisers indicated they will send you additional ormation. To obtain this, simply fill out the postage-paid card and drop it in any U.S. mailbox. Circle the numbers on the card responding to the numbers beside the advertisers in whom you are interested. Please allow up to six weeks for replies. Although h advertiser has assured us that it will respond to each request, the magazine is not responsible for any failure to do so. rthermore, the listing of an advertiser does not constitute any affiliation with, or endorsement by, the American Museum of tural History or NATURAL HISTORY Magazine.

32. Swan Hellenic Art Treasure Tours/ Exprinter. See the world through an educated eye.

33. Wilderness Travel. Wildlife tours, treks, sailing from Arctic to Amazon. Peru, Galapagos, Andes, Himalaya, Alps, Asia, Alaska, Africa. Small groups, expert leaders. Private trips arranged. Free color catalog.

34. Windjammer Barefoot Cruises. Discover the Caribbean with the ships that discovered the Caribbean, explore uninhabited islands, shop native villages, dive in blue waters. Send for free brochure.

That Ultrafright Smile

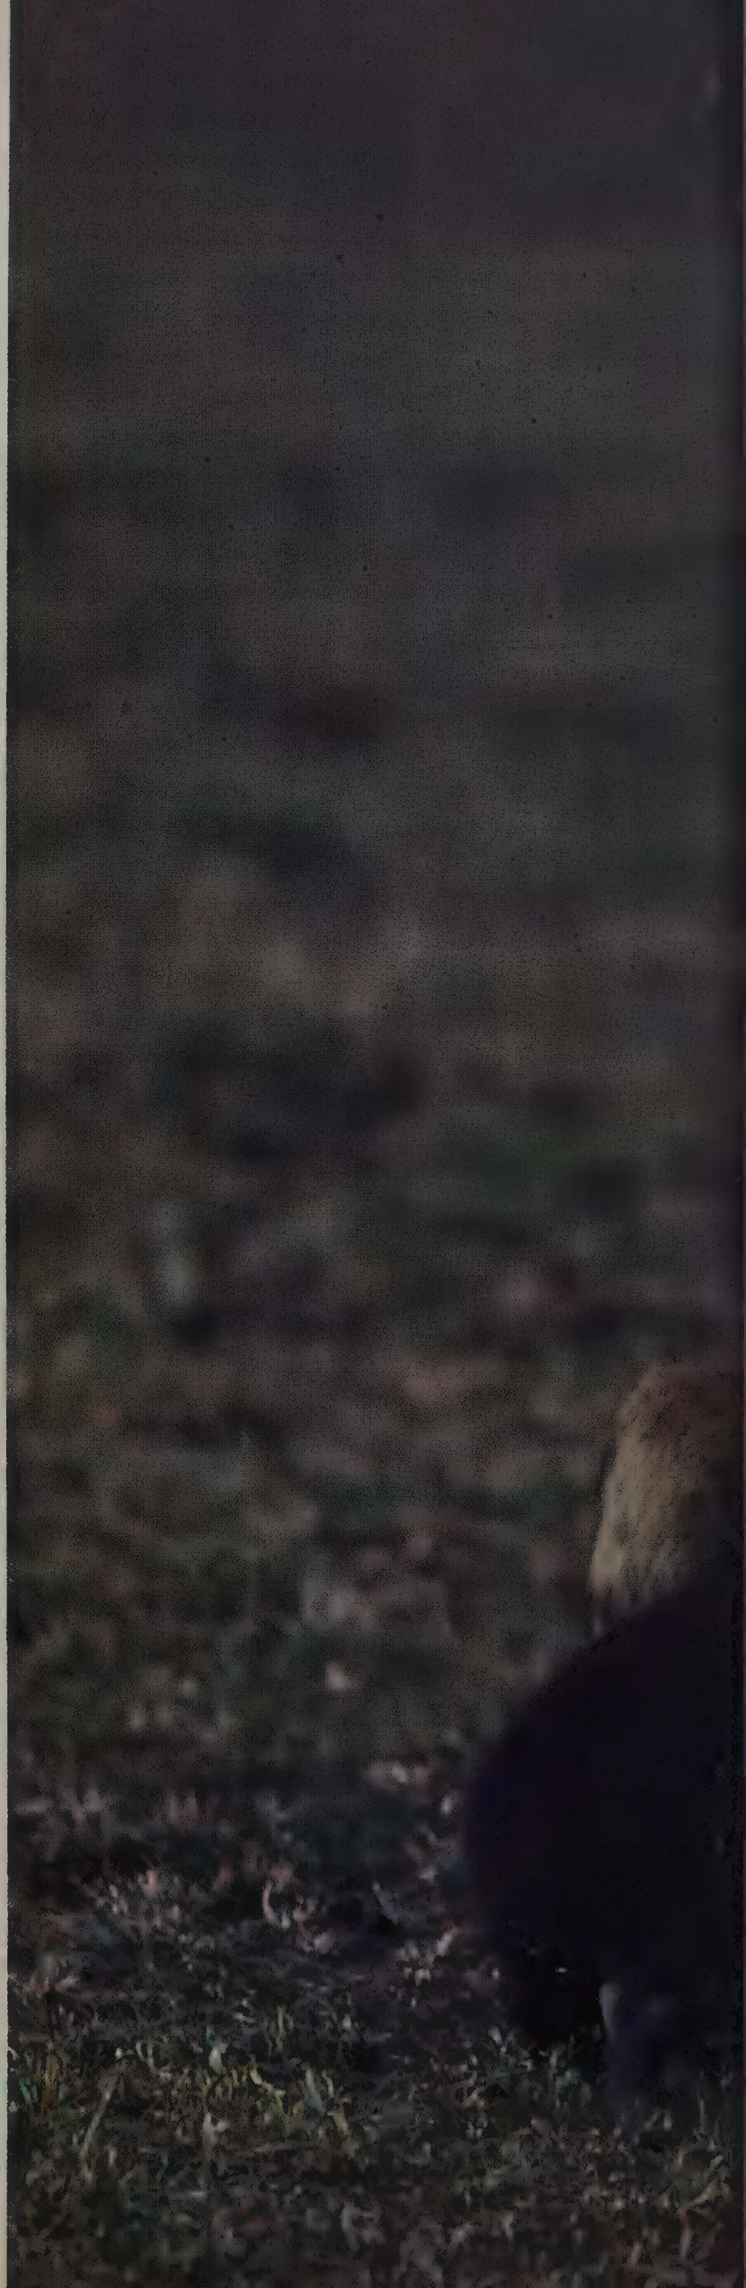
John Shaw came across this spotted hyena on Masai Mara, Kenya's national game reserve, while leading a group of amateur photographers on their first big game shoot. When he stopped his vehicle and got out, the hyena noticed him and sat down. Her two young cubs immediately dove for her nipples. Judging from the vegetation in the area, and the several hummocks near her, the den was probably nearby. So Shaw ordered his students out, knowing they were reasonably safe.

It's never wise to make a spotted hyena nervous. Among the deadliest of African predators, they can eat and digest whole carcasses, including skin and bones. The spotted hyena, which can hunt individually or in groups, feeds mainly on ungulates such as wildebeest or zebra, but there have also been fatal attacks on humans. Ernest Hemingway once referred to the hyena as the "biter-off of your face" in the night.

Spotted hyenas breed all through the year, and females usually have a litter of two, occasionally one or three. The cubs are nursed for twelve to sixteen months, at which point they are almost their adult size. Males reach sexual maturity at age two, females at age three. The animals live in large clans, with up to eighty individuals. These are made up, in turn, of subgroups containing two to ten hyenas.

It was near sundown when Shaw and his group came upon this family. To make matters worse, a storm was moving into the area. He didn't know if there was sufficient light to get the picture. But he did have one lens that he knew could work. It was a fast 400-millimeter, and setting it at f/3.5 gave him an exposure time of one-sixtieth of a second. Still, he wasn't happy about the setup because the hyena kept shifting position as the mouths on her shifted.

But then she did something wonderful. She yawned, a big, horrible yawn that showed those teeth that can crunch through a heavy bone. "Great," Shaw said, squeezing off three shots before the hyena closed her mouth.—*D.W.*



Photograph by John Shaw

DON'T MISS THE BOAT IN GREECE.

Come with Epirotiki. It's really the only way.

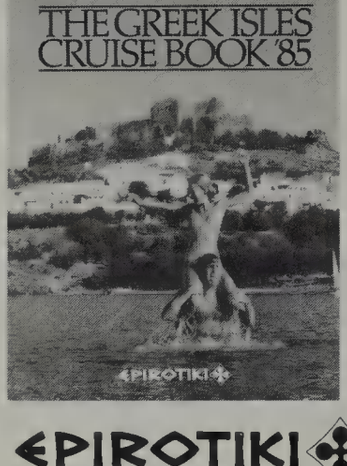
Although our home is in the Greek Isles, we happen to be the most popular fleet of cruise ships in the entire world. One cruise explains why.

Only Epirotiki takes you in such grand style to the Greek Isles plus Turkey or Egypt and Israel. With 2, 3, 4, 7 and 14-day cruises to choose from.

And all come with complete air/land/sea packages.

Send for our new 44-page brochure now.

It's all the Greece you'll ever need.



Epirotiki Lines, 551 Fifth Ave.
New York, NY 10176
Phone (212) 599-1750 or (800) 221-2470.

Please send new 1985 brochure at once.

Breadfruit (p. 34)

In 1787 H.M.S. *Bounty* set sail fron England bound for Tahiti, with Capt. Wi liam Bligh in charge. Its mission was t transport breadfruit trees to the Britis colonies, but constant storms, low food ra tions, and Bligh's harsh temper made th journey long and difficult. *Mutiny on th Bounty,* by C. Nordhoff and J.N. Hal (Boston: Little, Brown and Co., 193 many publications since), chronicles th voyage to Tahiti, the crew's stay on the is land, and the historic return journey, dur ing which Bligh and eighteen loyal sea men were cast off in an open boat. Thre films have been made about this famou mutiny. The first, *Mutiny on the Bount* (1935), starred Charles Laughton as Cap tain Bligh; Trevor Howard was Bligh i the second version (1962). Bligh's princi pal antagonist, Fletcher Christian, wa played by Clark Gable in the first film an Marlon Brando in the second. *The Bount* (1984) featured Anthony Hopkins a Bligh and Mel Gibson as Mr. Christian Lord Byron wrote a poem about the leg endary mutiny, "The Island; or Christia and his Comrades" (see *The Complet Poetical Works of Byron,* Boston: Hough ton Mifflin Co., 1933), based on Willian Bligh's *A Narrative of the Mutiny an Seizure of the Bounty, in the South Seas in 1789.* Captain Cook much admired th breadfruit; during his long South Sea voy ages, he reduced the incidence of scurv among his sailors by making breadfruit a essential part of their diet. See his writing about the breadfruit in *The Journals o Captain James Cook,* edited by J.C Beaglehole (New York: Cambridge Uni versity Press, 1955). The letters of Josep Banks, the prominent British naturalis who accompanied Cook on his first expe dition, are in the collections of the Britis Museum and have been edited by W.R Dawson: see *The Banks Letters* (London The British Museum Publications, 1958) J.M. Purseglove summarizes the botan of the breadfruit in *Tropical Crops: Di cotyledons* (New York: John Wiley an Sons, 1968). On a lighter note, Na Lim Kokua, the Helping Hands of the Pacifi Tropical Botanical Garden, publishes

xteen-page booklet containing thirty-ree breadfruit recipes. *Breadfruit (Ulu): ses and Recipes* is available for $2 from a Lima Kokua, Pacific Tropical Botani-l Garden, P.O. Box 340, Lawai, Kauai, awaii 96765.

hickadees (p. 42)

In winter, flocks of chickadees are ade up of two sorts of birds: those that ay in a single flock (the regulars), and ose that move from one flock to another he floaters). S.M. Smith investigates the tricacies of the flock status system and e breeding strategies behind it in "Flock witching in Chickadees: Why Be a Win-r Floater?"(*The American Naturalist,* ol. 123, pp. 81–98). Smith also looks at e roles of floaters in "The 'Underworld' a Territorial Sparrow: Adaptive Strat-gy for Floaters" (*The American Natu-alist,* vol. 112, pp. 571–82). Also interest-g is J. Ekman, G. Cederholm, and C. skenmo's "Spacing and Survival in Win-r Groups of Willow Tit *Parus montanus* nd Crested Tit *P. cristatus*—A Removal tudy" (*Journal of Animal Ecology,* vol.), pp. 1–9). For a concise account of nickadee natural history, see part II of .C. Bent's classic *Life Histories of orth American Jays, Crows, and Tit-ice* (New York: Dover Publications, 964). N.B. Davies's "Ecological Ques-ons About Territorial Behaviour" forms napter 11 of *Behavioural Ecology,* lited by J.R. Krebs and Davies (Sunder-nd, MA: Sinauer Associates, 1978, pp. 7–350).

acandon Maya (p. 50)

This issue's article on the Lacandon is xcerpted from *Gertrude Blom*, edited by . Harris and M. Sartor (Chapel Hill: niversity of North Carolina Press, 984). This is a collection of 104 black-nd-white photographs of Indian tribes in e Mexican rain forest, taken by Blom er a forty-year period. Essays by Blom nd others offer insight into her life and ork and also discuss the Maya of Chia-as and the destruction of tropical rain rests. A good description of the rain for-ts and the people who live in them, geared for a popular audience, is *Jungles,* edited by E.S. Ayensu (New York: Crown Publishers, 1980). Several chapters of *The Sinking Ark,* by N. Myers (New York: Pergamon Press, 1979), are devoted to the problems of plant and animal extinctions in tropical rain forests. *In the Rainforest*, by C. Caufield (New York: Alfred A. Knopf, 1985), describes how aboriginal peoples are being driven out of their homes in the rain forest because they stand in the way of "progress." An excerpt appeared in the January 14, 1985, *New Yorker. Technologies to Sustain Tropical Forest Resources* (Washington, D.C.: U.S. Congress, Office of Technology Assessment, OTA-F-214, March 1984, Government Printing Office Stock Number 052-003-00943-9) is a collection of papers on the status and future of the world's tropical forests. This well-documented, 344-page volume is available in paperback from the U.S. Government Printing Office for $10. For a free 35-page booklet summarizing the report, write to the Congressional Relations and Public Affairs Office, Office of Technology Assessment, U.S. Congress, Washington D.C. 20510. F. Blom and G.D. Blom briefly survey all aspects of Lacandon Maya life in "The Lacandon," in *Handbook of Middle American Indians,* vol. 7, edited by E.Z. Vogt (Austin: University of Texas Press, 1969, pp. 76–97). The earliest, but still the most complete, ethnographic study of traditional Lacandon culture is A.M. Tozzer's *A Comparative Study of the Mayas and the Lacandones* (New York: Macmillan Co., 1907; reprinted in 1978 by AMS Press, New York). V. Perera and R.D. Bruce study cultural changes in the Lacandon Maya settlement of Najá in *The Last Lords of Palenque* (Boston: Little, Brown and Co., 1982). The effects of economic development on South American Indians are explored in S. Davis's *Victims of the Miracle* (New York: Cambridge University Press, 1977). A number of organizations are active in the fight to protect the rights and environments of the world's indigenous peoples; the following three publish either a journal or periodic newsletters or bulletins: Cultural Survival, 11 Divinity Avenue, Cambridge, MA 02138, publishes *Cultural Survival Quarterly;* Anthropology Resource Center, P.O. Box 152266, Washington, D.C. 20003-0266, publishes *The Global Reporter: A Journal of People, Resources, and the World;* and Survival International, 29 Craven Street, London WC2N SNT, England, publishes frequent action bulletins for its members (the U.S. branch is located at 2121 Decatur Place NW, Washington, D.C. 20008).

Foraminifera (p. 60)

Most introductory geology and paleontology textbooks contain some information about foraminifera and their history on earth. For example, J.R. Beerbower's *Search for the Past* (Englewood Cliffs: Prentice-Hall, Inc., 1969), an introduction to paleontology, devotes about ten pages to the forams. Oceanography texts are also helpful, particularly for data on planktonic forams. Some scientific articles on these tiny creatures include: "All About Ooze," by N. Rosa (*Oceans,* November 1979, pp. 30–33); "Neglected Amoebas in Culture," by J.J. Lee and H. Freudenthal (*Natural History,* December 1963, pp. 54–61); and "Corals and Coral Reefs," by T.F. Goreau et al. (*Scientific American,* August 1979, vol. 241, pp. 124–36). Although there are many more recent articles on mass extinctions, N.D. Newell's "Crises in the History of Life" (*Scientific American,* February 1963, pp. 76–92, also reprinted in *Scientific American Resource Library Readings in the Earth Sciences,* vol. 2, published by W.H. Freeman, New York, 1969) is known for the comprehensive range of organisms that it covers. Finally, see "Science and the Citizen: Seven Hypotheses" (*Scientific American,* April 1982, p. 80) for a short explication of Mesozoic mass extinctions.

Rita Campon

Erratum: In the August 1984 issue, *Natural History* failed to mention that the fossil ammonite specimens shown in photographs on pages 34–35 and 37 were from the Yale Peabody Museum.

Be a Better Gardener

RECYCLE all your Brush, Weeds, Leaves, Old Crops, Cut Grass, Dead Flowers, etc. into:

- **RICH COMPOST**
- **SPREADABLE MULCH**
- **DECORATIVE WOOD CHIPS**

The rugged KEMP Shredder/Chipper devours almost *anything* organic...reducing it into *millions* of tiny pieces in *seconds* (including branches up to 3" thick!).

Enjoy super-rich soil...a mulched garden that is virtually *weed-free* and beautifully landscaped grounds. Do it all, quickly and easily, with a KEMP.

- Built to last a lifetime
- Many sizes to choose from
- Money-back guarantee

Authors

Some of the projects **Gerald Oster** and **Selmaree Oster** (page 34) have worked on in Haiti are symbolized in their "photo," actually an eighteen-inch-diameter papier mâché plaque by the Haitian mask maker Lionel Simonis. Gerald Oster holds a goat to illustrate a program of confining farm animals to pens, important in Haiti, where overgrazing by farm animals causes devastating soil erosion. The Peking duck in Selmaree Oster's arms relates to a fish farming project. Pisciculture can provide desperately needed protein to the Haitian population, and duck droppings fertilize the pond algae on which the fish feed. The Osters' main medical project in Haiti consists of developing a botanical approach to eliminating the region's malaria-carrying mosquito. They have also

worked jointly in reproductive biology at the Mount Sinai School of Medicine of the City University of New York, where they discovered a method for detecting signs of impending human ovulation.

Susan M. Smith (page 42) says, "I became a rabid bird watcher at the age of nine when I saw a golden-crowned kinglet on my way to school." Chickadees, the subject of her article in this issue of *Natural History*, captured her interest because they are one of the few common winter songbirds in Winnipeg, Manitoba, where she was born and spent her early childhood. Smith is currently an associate professor in the Department of Biological Sciences at Mount Holyoke College in South Hadley, Massachusetts. She did her undergraduate work at the University of British Columbia in Vancouver and received a doctorate in zoology from the University of Washington in Seattle. Among her free-time activities, Smith lists cross-country skiing; she points out, however, that although she enjoys the sport, she is emphatically a neophyte.

Butterfly Notecards

Send your thoughts to your friends on the wings of six delicate species of butterfly. Produced from extremely rare 18th and 19th century hand-colored engravings in the Rare Book Room of the American Museum of Natural History, these notecards help support the work of the Museum as well. Each group of ten notecards comes with envelopes, and is in its own packet. The entire set of three packets is available for $13.50. Individual packets available at $4.95 each.

☐ Yes, I would like to order ____ complete sets of notecards at $13.50 each including shipping.

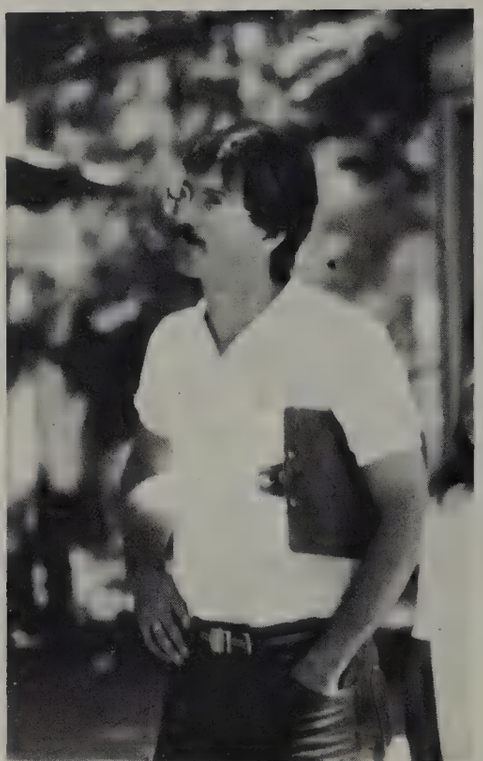
Authors, continued

"I first went to Chiapas, Mexico, in 1974 to study the population ecology and rain forest agriculture of the Lacandon Maya and soon realized that their rain forest environment was literally being burned into extinction—the Lacandon Maya were a forest people soon to be without a forest," explains **James D. Nations** (page 50). "I was determined to study ways to avoid that destruction." In 1979, Nations returned to explore indigenous agricultural systems as alternatives to beef cattle production, the major cause of rain forest destruction in Mexico and Central America. Since the fall of 1981, he has been a senior researcher with the Center for Human Ecology, an independent environmental research and consulting group in Austin, Texas, that focuses on the Latin American tropics. Nations earned his doctorate in anthropology from Southern Methodist University.



"I am not an English teacher," insists **John Shaw** (page 90), even though nobody said he was. Sixteen years ago Shaw, who had been insisting that to himself for some time, decided to scrap his college teaching career (American literature—transcendentalism) and pursue wildlife photography. And every now and then, he still doesn't mind clarifying what he is not. "I *was* an English teacher," says Shaw, "who either went good or went bad, depending on how you look at it." Lots of magazines think he went fine. Shaw has published in *Audubon*, *National Wildlife*, and a stack of others. Last year he published *The Nature Photographer's Complete Guide to Professional Field Techniques* (New York: Amphoto), and for the past few years he has been holding summer workshops in Kenya on big-game photography. If these last two credits sound of the pedantic sort, they probably are. But, as Shaw would point out, they are not English teaching credits, a difference that has made all the difference.

Shattering old ideas about safety.

The energy-absorbing steering column, multi-beam headlamps, side-guard door beams and windshield safety glass were GM-pioneered.

Today, we're working to develop new ways to build-in safety.

Our latest effort: the GM "Inner Shield" windshield. It's in limited production now. It's a flexible, two-part plastic layer that's applied to the windshield's inner surface to help protect you against facial cuts and lacerations from broken glass.

Exclusively GM, it's just one more way we are helping to protect the most important part of our cars: You and your passengers.

We believe in taking the extra time, giving the extra effort and paying attention to every detail. That's what it takes to provide the quality that leads more people to buy GM cars and trucks than any other kind.

That's the GM commitment to excellence.

GM

Nobody sweats the details like GM.

A Bite to Remember

One strike and you might be out, if you accidentally meet a viper in a rain forest

by Robert K. Colwell

After a long morning of research, my companion Bill Sheehan and I headed back to camp down a rain forest ravine in Corcovado National Park, a rugged wilderness in southern Costa Rica, where I had come to teach a course in tropical biology. I didn't see the snake until it was too late. As I jumped from one sand bar to another in the stream bed, I passed a buttressed tree, rooted about waist level in the stream bank. What I hoped was a thorn jabbed the biceps of my right arm, just below the short sleeve of my shirt. But then I saw twin slits in my skin, oozing yellow venom mixed with blood, and caught sight of a thick snake recoiling on the bank. I had always assumed that the strike of a large viper would hit like a fist studded with knives—not like the graceful, even gentle hypodermic pricking I had felt.

"Bill," I yelled upstream, "I've just been bitten by a *Bothrops atrox!*" I frankly have no idea why the Latin name came first to mind. The English name for this snake is actually French—*fer-de-lance*—for the shape of the head. The Spanish name, at least in Costa Rica, is *terciopelo*—"velvet"—for the rich black and tan colors and the sheen of the scales. The Latin name has officially been changed to *Bothrops asper* since I first learned it.

As Bill approached on the run, I had to divert him or he would have taken exactly the route I had followed, risking a second strike. By the time he arrived, I had removed the mesh bag of my insect net for him to tie as a constricting band above the bite on my arm, while I kept an eye on the snake. (A constricting band is a strip of cloth kept loose enough to insert one finger underneath it. The band must be released for ninety seconds every ten minutes to allow surface circulation. If bound so tightly that deep circulation is cut off, the band becomes a tourniquet—which can do more harm to a limb than a snakebite.) Then, breaking the rules, I ran a half mile to the park headquarters, rationalizing (incorrectly) that running would spread the poison only if the bite were in a leg. Bill stayed behind to kill the snake so it could be positively identified. I yelled for help as I passed the outdoor eating shelter at park headquarters, and the tables emptied.

During the next hour and a half I lay on a bunk in a park guard's room, not at all sure of my future. There was a great deal of scurrying about as three different sets of antiserums, with three conflicting sets of instructions in two languages, were gathered. My friend and fellow professor Barbara Bentley took charge, kept the rest of the course members busy and at bay, and began the sensitivity tests for horse-serum allergy on my left forearm.

To produce antiserum, or antivenin, horses are injected with sublethal doses of snake venom, inducing the formation of antibodies to venom proteins. Whole serum from the blood of these horses is reduced to a freeze-dried powder, which is easily reconstituted with sterile water when needed to treat snakebite. The production of snake antiserums is the responsibility of the Instituto Clodomirio Picado in San José, Costa Rica's capital city. Antivenins specific to local snakes are produced there and carried at all times during courses given in the field. The antiserums, one for vipers and one for coral snakes, are also readily available over the counter in drugstores throughout Costa Rica. While I waited the prescribed twenty minutes for the skin reaction test on my left forearm, which would determine if I could safely given antiserum, I watched my right a swell to twice its usual circumference a thought about all the things I am aller to—celery, watermelon, walnuts, poll guinea pigs . . . and horses (but not to th blood, I hoped).

Soon Bill came in to ask if I wanted see the snake, which he had killed wit machete after pinning it with a log. I s yes. It was in two pieces, the head seve from the four-foot-long body. I stared a and felt the weight of its thick body. It v a beautiful creature, wondrously adap for its life as a predator in ambush. Ha Greene, my colleague at the University California at Berkeley, has studied daily life of these snakes by carefu putting miniature radio transmitters do their throats and following their mo ments in the forest. The marvelously ca ouflaged fer-de-lance can sit motionless the same spot for days or even weeks, w ing for a meal to wander by.

Like other vipers, the fer-de-lance u not only its eyes but also special heat-se ing organs (known as pits, or Jacobso organs) to detect potential prey and to rect a strike. The venom injected in a s gle strike is enough to kill a victim the s of a large rabbit within minutes. Sna venom is extremely complex, vary greatly with the species of snake, its a and even its geographical origin. Unl the venom of coral snakes, fer-de-la venom has no direct effect on the nerv system but digests muscle, destroys blo cells, and causes hemorrhaging and m sive edema (swelling).

As I touched the body of the snake t bit me, I felt no rancor—only sorrow what must have been a case of mistal identity. The snake had struck from

"We went to see windmills."

"And fell in love with the castles."

Nowhere else in Europe will you find as many unexpected surprises as in Holland.

Where else can you visit a working windmill in the morning, and in the afternoon tour a medieval castle? We have more than 300 fairy-tale castles, all guaranteed to enchant and delight you.

You'll also find we have more canals than Venice to sightsee on.

There are more than 700 museums to walk about in—Van Gogh has one all to himself!

You'll find great orchestras to listen to. Famous ballets to see. And Dutch hospitality everywhere you go. Another pleasant surprise, almost all of us speak English!

Spending time in Holland right now means spending less money. Since your dollar goes further, you'll get great shopping bargains, including duty-free shopping at Amsterdam's Schiphol Airport.

Low-priced tours of Holland and Europe.

Now KLM offers low air fares to Amsterdam and a wide variety of low-priced tours of Holland and Europe that *start* in Amsterdam. You can tour by rental car, train, motorcoach, cruise ship, camper, even by bicycle!

For information, return this coupon for the KLM/Netherlands Board of Tourism Vacation Value Kit. Then see your travel agent.

The Fitness Master LT-35

TOTAL SYSTEM FOR CARDIOVASCULAR FITNESS.

Simulates cross-country skiing, regarded by fitness authorities as the top cardiovascular exercise. Rated higher than jogging, swimming, biking or rowing.

- Fluid motion — no jarring impact on bones and joints. Avoids running related injuries.
- Excellent for weight control and body tone.
- Stable, unit rests flat on floor. Lightweight for portability. Weighs only 35 lbs.
- Easily stored. Folds to 5 inch height. Slips under bed or stands upright in closet.
- Can be used by men and women regardless of size or weight. Height and resistance adjustable.
- 30 day home trial. 2 year warranty.

The venomous fer-de-lance H.W. Gree

good distance off to one side of my path. Because the lower two-thirds of my body had been shielded from its perception by the river bank, the snake may have taken me for something small enough to eat—or perhaps only the exposed part of my arm, below the short sleeve, caught its attention. Someone had opened up the snake's stomach. It was empty, which meant that the venom glands had probably filled to capacity during the time the snake had lain in wait for prey.

Every tropical biologist watches for snakes. After years of fieldwork, we watch in the same unconscious way that the experienced driver watches for a drunk on the freeway. Drunk drivers on freeways, in fact, are much more common than large poisonous snakes within striking distance in tropical forests. I calculate that one such snake is seen for every 400 to 800 person-hours in the field in Costa Rican rain forests. During the fifteen years of courses given there by the Organization for Tropical Studies, there were some 450,000 person-hours in the field without a venomous snakebite. Unfortunately, I had broken that record.

The antivenin allergy test was negative—I could safely receive the antivenin. My friends injected 30 cc into my backside and another 5 near the bite. (The injection in my arm was not only excruciating but, I later learned, could actual have been harmful, by further blocking l cal circulation. Antivenin should alwa be injected in a large muscle away fro the area of the bite. In case of sensitivity horse serum, there is an alternative, a though somewhat less effective serum- made from sheep blood—for Costa Rica snakes, but we did not have it.)

Meanwhile, the park guards had use their brand-new radio to call in a fou seater bush plane from San José—no mally about a twenty-five minute fligh In spite of bad weather, it made it to o grass airstrip an hour and a half after t bite, and I was carried aboard. One of t students in our group who had experienc treating shock accompanied me to Sa José, Adrenalin kit in hand. The flight w an ordeal. As the air pressure fell, the rel tive pressure inside my arm rose. We ha been at sea level, and San José is at 8,00 foot elevation, so landing didn't he much. Moreover, the air was choppy, ar substances in the venom that cause diso entation and nausea had taken hold. I w definitely losing control.

An elderly nurse greeted my entry in the emergency room at the hospital wi an intravenous rig. I was so near the end my rope that I must have let out a c when she put the needle in, because sh said sternly, *"Silencio, Señor! Esto es*

Aren't you glad there's a Charter Collection?

Charter Collection
Natural Fiber Sportswear with a luxury look
Matka.
The wild side
of silk.
Hear that magical
purr "silk", and you
think smooth, and
brilliantly colorful.
But there is another kind
of silk, a wild kind,
produced by wild silkworms
in the deep jungles of India.
A silk that doesn't like to be
dyed, so is usually left in its
tannish natural state. And
won't be spun into anything
smooth, because it clings
stubbornly to its slubs. It is
called Matka.
When one of our buyers
first brought this Matka to
us, we realized it would
make a wonderful warm
weather sportjacket.
Because, although Matka is
wild, it still retains the
superior coolness, strength
and drape that make silk the
acknowledged aristocrat of
the natural fiber world.
Our Matka
Silk Jacket.
This jacket is fast becoming
a new staple of the
traditional wardrobe. It can
dress you up or down, and
its undyed natural color
opens up a wide field of play
for your accessories. 100%
wild Matka silk, tailored
with full Charter features.
Professionally dry clean
only. Made in USA and
Imported. Men's Regular in
sizes 38-46 (no 45); Long in
40-46 (no 45); Short in even
sizes 38-44.
Regular 3595J15

hospital!" I vividly remember the remark because it forced me to get a firm grip on myself for the first time since boarding the airplane. Besides, it marked the moment when I began to feel that I actually would survive if I followed the orders of this crusty *comandante* of the emergency room. A huge dose of Demerol disappeared down the tube into my grateful body, followed by another 60 cc of antivenin, antitetanus serum, and several million units of penicillin. (One cubic centimeter of fer-de-lance venom contains about two million bacteria of a half dozen species, and tetanus is common on viper fangs.)

For the next three days I watched a dozen fellow humans come and go in the intensive care room, where I was kept because of the threat of bleeding. None of the other patients stayed for more than a day, and the only one who was conscious could not talk. In spite of the excellent care and facilities, a victim of a road accident and a man who suffered repeated heart attacks died as I watched. Then there was Alejandro, age sixteen, who had ruptured his esophagus while vomiting after drinking too much with some older friends. He was later to be my ward mate.

I think you are supposed to be unconscious when in intensive care. The lights were left on twenty-four hours a day and the staff chattered constantly to keep themselves alert and sane when nothing urgent was happening. I was grateful for my fluency in Spanish, but even so, I had difficulty getting anyone to tell me what was going on in my body or what dangers were keeping me in intensive care. Because my right arm was held in traction to keep the swelling down, I had to lie flat on my back under the fluorescent lights. From the wall clock I knew how much time had passed. There were no meals to punctuate those days, just changes of the glucose drip. Snake venom includes something that makes you too nauseated to hold even water down, let alone solid food.

No matter how unpleasant the nausea and how intense the pain, it is usually the "hemorrhagic fraction" of the venom of the fer-de-lance and related snakes that ultimately kills its natural prey and is responsible for most human fatalities as well. Victims bleed to death. The bleeding can be from internal organs (the staff in intensive care constantly checked my urine for the presence of blood) or from the eyes or ears—anywhere but from the bite itself, which is too swollen to leak from the tiny fang wounds. Rattlesnake venom, on the other hand, does not have much effect on the ability of blood to clot—hence the traditional recommendation to cut across the fang wounds and suck out the venom. It is mortally dangerous to cut anyone bi ten by a fer-de-lance or one of its relative of the genus *Bothrops*.

Despite the immediate and prope treatment with antivenin, the low platele count and the loss of certain clotting fac tors in my blood were sufficient to keep it clotting time eight times normal for th first day (hemophiliacs have a clottin time of about half that). Fortunately, sprang no leaks while my blood was heal ing, although the hospital staff was read for any emergency with appropriate drug on a tray at my side. However, the i.v. ha to be moved often to a new site because o local hemorrhaging; when there were n more usable veins in my left arm, my leg and even my feet were pressed into ser vice. I later discovered that an appeal ha gone out for O-negative blood, to matc mine.

My right arm continued to swell an discolor for two days; the swelling eventu ally included my right shoulder and th whole right side of my torso, and I coul no longer keep my head from tilting to th left. In addition to the clotting problem another concern was circulation to th lower part of my right arm—past the im mensely swollen area of the bite. Th pulse in my hand was checked every hou Had it weakened sufficiently, the doctor said they would have had to "make som deep incisions to release the pressure o the deep arteries" (a fasciotomy) to sav the arm itself. They told me it would b helpful to make a fist now and then. made a great many fists, and my puls stayed strong enough.

Moving from intensive care to a ward— with a real bed, real food, and lights tha went out at night—was like coming bac to Earth after spending three day strapped into a cramped spacecraf plagued with disasters. My arm was stil hoisted up on a rope, and there were stil frequent and ever more creative change of site for the i.v. tube, but I now ha peers, alive and awake, to talk to; visitor were allowed (first, my wife, Mary-Claire who had come from California, and late other friends); there were meals, sunrise and sunsets, and at last, the swelling wa beginning to subside. Alejandro of th ruptured esophagus was already there complaining about the bland liquid diet h was allowed. His friends smuggled i small cans of fruit juice, cookies, an candy bars, which he hid under some mag azines and enjoyed when the nurses wer out of sight. My euphoria was short-lived On my second day in the ward the serum sickness began.

It started with wall-to-wall red welts— hives—on my chest. The reaction soo

A major new work in a rare and beautiful porcelain art form.

The Empress of China

AN ORIGINAL FRAMED PORCELAIN BY THOMAS WESLEY FREEMAN

Handsomely framed, ready for immediate display. Shown smaller than actual size of 13¼" by 10¼".

© 1985 FP

Available by direct application only.
Please mail your application by May 31, 1985.

o art form captures the majesty of the sea in ıite the same way as an original framed orcelain. For these remarkable portraits, eated in past centuries by some of Europe's ost gifted artists, possess exceptional pow-. They are consummate examples of marine t. Painstakingly crafted. Handsomely amed. And difficult to acquire today.

Now Franklin Porcelain announces an outanding new work in this distinguished traition of porcelain artistry. "The Empress of hina," by Thomas Wesley Freeman.

great marine artist's first work in porcelain

homas Wesley Freeman is one of the most ifted artists of our time. A member of The merican Society of Marine Artists, his work as been exhibited at Washington's prestigous Atlantic Gallery and is in the collection f former President Gerald R. Ford.

Now Freeman has turned his exceptional talents to the creation of his *first* work of art in porcelain. An extraordinary portrait that commemorates a major event in our maritime history—the 200th anniversary of the arrival of the first American vessel in a Chinese port. And America's entry into the China Trade.

"The Empress of China" is a masterful work that recaptures all the pageantry of that historic moment. And to re-create every line, every nuance of Freeman's art, this dramatic scene will be meticulously crafted on a "canvas" of fine imported porcelain, then mounted in a finely finished wood frame to which a brass nameplate will be added. The result is a showpiece of marine art to display with pride today and in the years to come.

"The Empress of China" will be available exclusively from Franklin Porcelain and only by direct application. The price is $135 and there is a limit of one per person. To acquire this original framed porcelain, mail the attached application to Franklin Porcelain, Franklin Center, PA 19091, by May 31, 1985.

spread over my shoulders and down my back, cropped up on my thighs and buttocks and then on my face and scalp, all within a few hours. Everything burned; everything itched. The nurses had to wait for orders from a doctor, of course, before they could do anything, and although I'm sure they knew what was happening to me, they weren't willing to tell me. I assumed that I had suddenly developed an allergy to one of the drugs they were giving me—penicillin, Demerol, or codeine. More than four days had passed since the horse serum was pumped in, so that couldn't have been the cause. By good fortune, the physician on rounds the next morning was Dr. Falcon, an immunologist, who was delighted to explain my condition to the four medical students touring the wards with him. When he learned that I was a biologist, he included me in his Socratic teaching session, fortunately asking me questions commensurate with my amateur status as an immunologist: "Now, Dr. Colwell, what happens when a foreign protein enters the body?" "Antibodies." "Señorita Gomez, how many days until the antibody titer equals the concentration of antigens?" "Four to six."

So the cause of the welts was the horse serum after all, and my gigantic case of hives was a perfectly normal reaction to having 90 cc of some other species' serum protein added to my own xenophobic system. Serum sickness, though, is not an allergic reaction, in the proper sense. The hives appear when human antibodies reach a concentration about equal to horse antigen. Each antibody molecule couples with an antigen molecule. These complexes are unfortunately not soluble in the blood, so they are deposited in capillary beds throughout the body, where they cause hives and, in more severe cases, produce other more dire, internal reactions (such as kidney failure). The antibodies, however, continue to form and link up with existing complexes, which go back into solution in the blood when there are two antigen molecules attached to each antibody molecule.

All this I learned in my ward bed from Falcon, the friendly immunologist. He also reassured me that everything I had experienced was normal for a properly, promptly treated viper bite, and that I was lucky there was not more tissue damage. He told me that, in Costa Rica, there are some five hundred bites from poisonous snakes each year—about one for every 4,500 people. Three-quarters of these bites are caused by the fer-de-lance. Before the development of specific antivenins, the death rate was high. Nowadays, virtually all victims receive medical treatment, and only 3 percent die, although a larger percentage suffer some permanent disability.

Fortunately, Falcon's knowledge of immunology had a practical side. He ordered generous doses of cortisone and antihistamine added to my i.v. cocktail—the cure for the cure for the snakebite. The hives slowly subsided, and the cortisone dose was decreased daily for the following ten days. (If a high dosage is withdrawn abruptly, the endocrine system goes haywire.) It became clear that there would be no severe damage to my arm and no surgery was needed to make it functional again. Nine days after I had entered the hospital, I felt well enough to talk my way out, on the condition that I take it easy and use the medications according to a complicated ritual.

My arm was still quite unusable, very stiff from a large internal clot in the area of the bite, where a good proportion of my original platelets and clotting factors lay entombed. The area of the clot, perhaps six inches long and four wide, was very hot for about six weeks, as my white blood cells digested the clot. Eventually, my arm was essentially as good as new. When I left the hospital, I spent a fine day in the countryside with my wife, breathing real air and taking stock of life. She had to leave for California the next day to return to our five-year-old daughter, but I stayed in Costa Rica to pursue some field research I had planned with a group of my graduate students from Berkeley, who were scheduled to arrive in a few days. I was to go through a period in which every step in the rain forest took courage, but gradually my fears lessened.

On my third day out of the hospital, the course I had been teaching ended, and all my colleagues and students arrived together in San José. I was waiting for them with my arm in a sling, but alive and well. They greeted me with great intensity, partly due to relief that the pessimistic predictions that had reached them in the field had not come to pass and partly, I believe, from pride in a job well done—each of them had contributed to saving my life after the fer-de-lance bite. But something else was also involved. What happened to me could just as well have happened to any one of them, and they sensed that from the start. Their joy was for their own lives as well as mine. That night we all went dancing. I didn't dance much, but I can't remember when I've enjoyed it more.

Robert K. Colwell is a professor of zoology at the University of California at Berkeley.

low, let's restore Civil Justice.

Year after year, our civil justice system has become slower. More costly. Less fair to the very people it was meant to help.

We all pay the price. Some of us pay in the frustration of waiting for a case to end, or by seeing a settlement eaten away by legal costs. All of us pay in the form of higher taxes and insurance premiums.

Experts agree on the urgent need for civil justice repair. Chief Justice Burger has criticized "the high cost of legal services and the slow pace of justice." Derek Bok, president of Harvard and former dean of Harvard Law, has called our legal system "the most expensive in the world."

A 1984 Rand Corporation study of thousands of asbestos-related lawsuits shows how serious the crisis has become. Cases closed took an average two years and eight months, with 11 percent taking six years. How much money went to asbestos victims? Only 37 percent of the expenses and compensation paid by defendants and insurers. The other 63 percent went to pay litigation costs.

Can anything be done? We think it can.

We're the Insurance Information Institute. Our members, property and casualty insurance companies, are vitally involved in this issue. They've joined with others–doctors, lawyers, government officials, business leaders–in coalitions of concerned citizens. Together, they're developing new solutions. In many states, their ideas are being translated into action.

Our latest report, *The Civil Justice Crisis,* examines the reforms now being proposed. It tells how you can get involved. We'd like you to have a copy, free of charge.

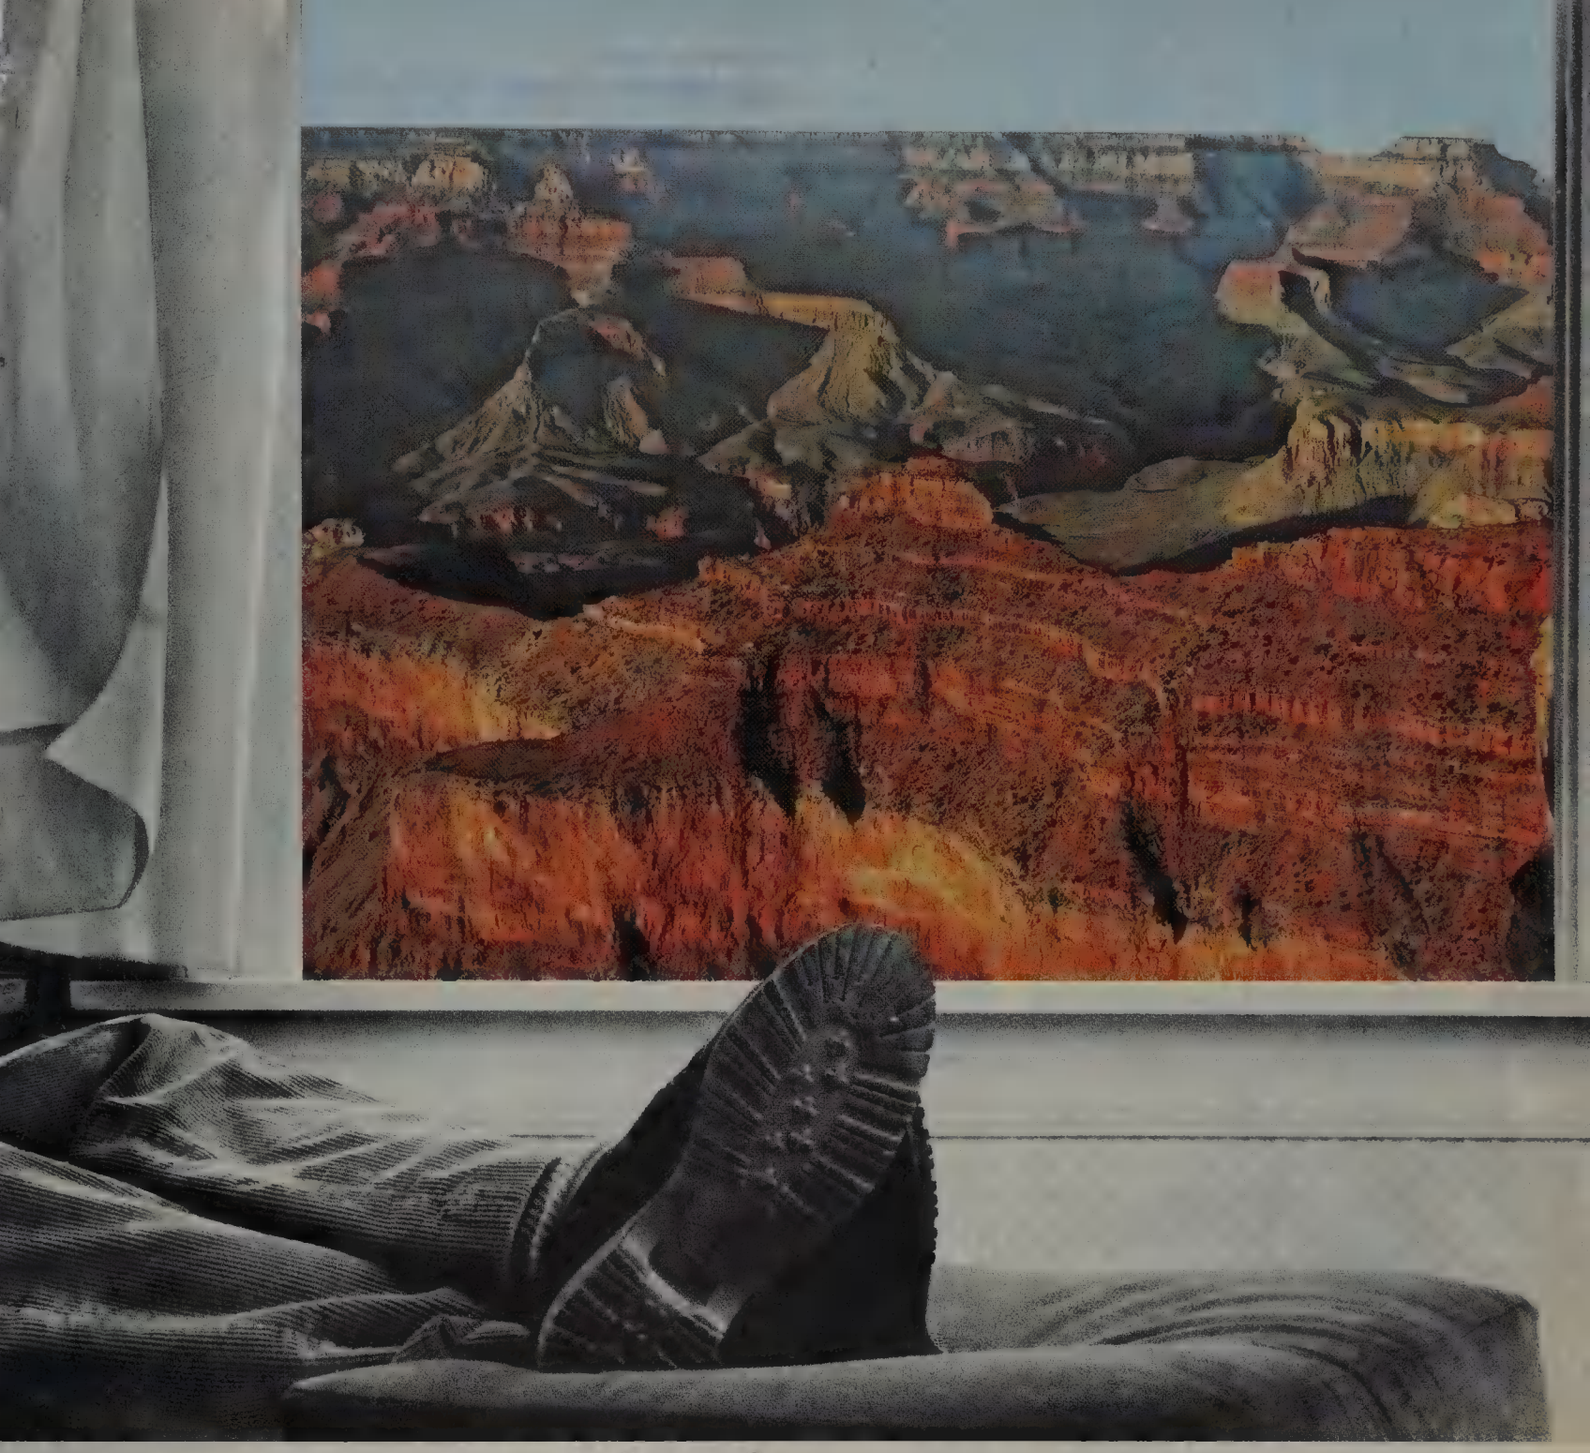
Bring the Grand Canyo

When you view the Grand Canyon, the minute-by-minute changes in the color and form of the land are spellbinding. You feel time slow down as your mind expands to take in the beauty of the scene. Yet you don't have to go there to capture this supercharged experience—all you need is The Grand Canyon from TIME-LIFE BOOKS.

As your tour of the canyon unfolds, you'll feel the exhilaration of riding bone-crunching rapids. As well as the eeriness of viewing sunrises over the mile-high eastern rim. You'll marvel at the strange forms of life that have evolved—such as the cacomistle with its catlike body and foxlike face. And these are just the beginning of the adventures you'll take in the AMERICAN WILDERNESS series from TIME-LIFE BOOKS. Adventures that will make you want to put on your hiking boots, grab your backpack, and head out on the trail.

Send for The Grand Canyon, the first volume in the series, and enjoy it for ten days. If you decide to keep it, you can further explore the wilderness in successive volumes. You'll see wild horses in The Great Divide, gigantic 26-foot wide sequoia trees in The High Sierra and an erupting Mt. Saint Helens in The Cascades. Plus, you'll receive a rugged nylon backpack, absolutely free, with your first purchase.

You have no commitment to buy anything. You can even send The Grand Canyon back



nto your living room.

hin 10 days and owe nothing. Otherwise, p it and pay only $12.95 ($15.95 in Canada) s shipping and handling. Future volumes ne one about every other month, always a free examination.
ep only the books you nt. Cancel any time ply by notifying us. Send in the reply card ay to experience some he most awe-inspiring nts on Earth.

EXPLORE THE GRAND CANYON FOR 10 DAYS FREE.

If card is missing, mail to: TIME-LIFE BOOKS, Time & Life Building, 541 North Fairbanks Court, Chicago, Illinois 60611

Yes, I would like to try The Grand Canyon as my introduction to THE AMERICAN WILDERNESS series. Please send it to me for a 10-day FREE examination. Also send me future volumes under the terms described in this ad. The backpack is mine to keep—at no extra cost—if I decide to purchase The Grand Canyon.

A Clock of Evolution

We finally have a method for sorting out homologies from "subtle as subtle can be" analogies

by Stephen Jay Gould

Metaphorical and biological meaning do not always overlap. Swans stand for silence, grace, and beauty; geese for honking stupidity. But the small biological space between these birds conflicts with their metaphorical distance. Matthew Arnold spoke for biology in his famous couplet from a poem appropriately titled "The Last Word."

> Let the long contention cease!
> Geese are swans, and swans are geese.

Geese, swans, and ducks belong to the order Anseriformes (Andersen's swan child—the ugly duckling—was reared, albeit unkindly, by a very close relative). Arnold's quip identifies the obvious members of this order, but what other birds reside with them in our classification?

The Anseriformes represent one alternative in an ancient and classic taxonomic debate that stretches back to Greek science and has only recently been resolved: Are flamingos geese (Anseriformes) or storks (Ciconiiformes)?

To a first approximation, a flamingo looks like a goose mounted on the long legs of a stork (see last month's column). When we pass beyond superficial appearances to details of anatomy and behavior, the problem only intensifies—impressive lists of subtle features seem to ally flamingos about equally with each contending group. Basic anatomy might grant a small edge to storks—based on features of the skull and pelvis, and even on details of intestinal convolutions. External form and behavior might give a little nod to geese—webbed feet, a honking voice, and above all, the serrated bill that permits a goose to chop vegetation but, in copiously exaggerated form, builds the complex filters of the flamingo's inverted jaws.

Such a knotty problem leads taxonomists to a search for more exotic criteria. Thus, debate also raged about the mallophagan (feather lice) parasites of flamingos and their possible role in sorting out the relationships of their hosts. Since these parasites are so highly specialized and poorly mobile, they tend to stay put and evolve in sync with their hosts. Since flamingos harbor three mallophagan genera found otherwise only on ducks, some systematists regarded this surrogate evidence as proof that flamingos are long-legged anseriforms. Others replied that the parasites of ducks and flamingos are too similar for such an interpretation—too much of a potential good thing. Even if ducks are the closest living relatives of flamingos, they argued, everyone admits an ancient evolutionary separation between the two groups. As a simpler hypothesis that would dethrone the Mallophaga as evolutionary yardsticks, perhaps flamingos simply received their infestation by "lateral transfer" from passing ducks sharing their waters—so that the similarity only records shared ecology, not evolutionary ancestry.

How do systematists resolve such thorny debates when each side can cite so many similarities in its support? The basic principle is easy enough (though devilishly tricky in application—hence the frustrating tenacity of debates about the classification of such "difficult" groups as flamingos). Biological similarity, defined as simple "looking alike," includes two entirely different reasons for being. Two organisms may look alike because both inherited a set of similar features from a common ancestor. Similarities based upon descent are called homologies. (We share hair, live birth, and a warmblooded physiology with chimps and mice by evolutionary history, or homology.) But features of two organisms may also look alike because both creatures evolved them independently in response to life in similar environments. Similarities based upon independent evolution are called analogies. (Birds and bats fly, and fish and whales swim, by analogy only. Bats and whales remain mammals by descent.)

Since we want our classifications to record genealogy, the basic principle of taxonomy is simple: Divide similarities into homologies and analogies, rigorously exclude the analogies as deceptive, and reconstruct evolutionary trees from homologies alone. So easy to say, but so hard to do. Bats present no problem; they are little more than flying "mice"—that is, mammals point for point, with one odd adaptation clearly geared to current function. But what can we do with creatures squarely between two groups in general appearance, and so replete with complex analogies that descent and immediate adaptation seem hopelessly confused in an inextricable jumble of characters?

Flamingos occupy this middle ground. No one has ever come close to a convincing separation of their homologies and analogies with geese and storks, the two leading contenders for their affinity. How can we tell whether they are basically geese grown long-legged in the shallow-water environments of wading birds or basically storks grown gooselike by independent evolution of bill ridges in feeding? In 1969, Yale ornithologist Charles Sibley wrote a long article on the relationships of flamingos (with K.W. Corbin and J.H. Haavie, in *The Condor*, vol. 71, pp. 155–79). He included a two-page chart covering a century of varying solutions. Most experts took the usual course in troubled waters: They kept all options open and hedged by creating a separate group for

Nothing feels like silk.

Now you can enjoy the luxurious comfort of 100% silk sportswear—at *factory direct* prices! In our FREE catalog.

100% Pure silk, Rediscovered.

Silk is the stuff of legends. For centuries only royalty in Asia enjoyed its luxuries. Now, with the reopening of China, the world's finest silk is again available. Skiers, outdoorspeople and connoisseurs of fine clothing have rediscovered silk as the world's quintessential natural fiber.

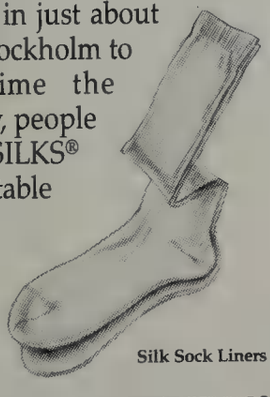
Silk Long John Shirt and Pants

Soft, warm and durable.

Silk is delicately soft to the touch, yet stronger per unit of thickness than an equal strand of steel. When dyed it holds its colors brilliantly, and will last for years. Many people consider silk clothing a lifetime investment.

Widest silk selection anywhere.

Our famous Silk Long Johns have been skiing, climbing, trout fishing, sailing, canoeing, bird watching, cold weather office commuting in just about every city from Stockholm to Seattle. Any time the weather gets chilly, people turn to WINTERSILKS® for soft, comfortable next-to-the-skin body insulation that is luxurious, soft, non-bulky and affordable.



Silk Sock Liners

We also offer an exclusive WINTERSILKS® line of woven silk sportswear: Silk Oxford Shirts in men's and ladies' styles, Formal Scarves, Silk Pillow Cases, Ladies' Silk Sashes, Silk Kimono Robes, Sleepytime Silk Pajamas, Silk Running Shorts, Silk/Cotton Sweaters, and 40 other exclusive silk items. There's not room to tell you about all of them here, so please call or write for our FREE color catalog.

Luxury you can afford.

At WINTERSILKS®, we deal directly with the finest silk knitters and weavers in China and the Imperial Far East. WINTERSILKS® garments are made to our specifications, then sold directly to you by catalog, without any middlemen, and at prices 15-50% below normal retail. Result: Quality, selection and savings you won't find elsewhere.

Tested on Mt. Everest.

Is silk really warm? We sent several dozen WINTERSILKS® glove liners to Mt. Everest. Here's what the experts had to say:

"I would personally like to commend you for producing a high quality product that, in my experience, has superior durability to any other glove liners I have ever used.

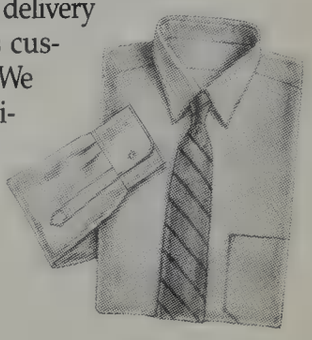
"Your silk gloves outlast synthetics several times over and provide equal warmth to bulkier knit pile and natural fiber gloves.

"A single pair of silk gloves, which most of us used exclusively, lasted the entire three and one-half months of the climb."

–Warren Thompson, 1984 Ultima Thule, Mt. Everest Expedition Leader
Seattle, Washington

You'll be happy. We Guarantee it.

Your satisfaction is our Job Number 1. It's not enough just to offer the widest selection of silk sportswear available anywhere at prices that make Seventh Avenue blush. We back up our products and prices with fast delivery and courteous customer service. We have an experienced full-time staff to handle returns, exchanges and daily questions. We offer a generous guarantee. We make it easy and carefree for you to shop by mail.



Silk Oxford Shirts

Immediate Delivery.

Our goal is to ship all orders we receive within 48 hours of receipt. If you live in New York or New Orleans, for instance, that means that your WINTERSILKS® package will arrive at your doorstep 5-9 days after you hang up your telephone, or 9-13 days after you mail in your order. (Add 2 business days if you live on the West Coast.) If you're really in a hurry, we offer Next-Day Express Delivery for a small extra charge. Around here, we take service seriously.

A FREE catalog for you.

To receive your FREE one-year subscription to the WINTERSILKS® catalog collection, simply fill in, clip and mail the coupon below, or call our Quick-Service Line:

1-608-836-4600.

To discover the luxurious world of silk, call or write *today!*

Silk is:

- Lighter than cotton, wool and many man-made fibers.
- The strongest of all natural fibers.
- Warmer by the ounce than most other fibers.

flamingos midway between geese and storks. A well-known cousin of Matthew Arnold's—Thomas Henry Huxley—headed Sibley's list. In 1867, Huxley opted for what Jules Feiffer once called the radical middle by placing flamingos in the Phoenicopteriformes, right after ducks and just before storks in his general classification.

But this taxonomic muddle has a happy ending. The problem has been resolved. In fact, Charles Sibley and his colleague Jon Ahlquist have nearly completed an evolutionary tree for all birds—the first group ever exhaustively treated by a method that can properly sort homology from analogy. Flamingos, by the way, are storks. (And I'm damned disappointed. My Audubon invert from last month works equally well whether flamingos are truly swans or merely convergent upon them. Still, I somehow developed the gut feeling that geese would win—so, by the way, did Sibley, when he began his work.) Sibley even feels that he can provide a date—forty-eight million years give or take only a bit—for the divergence of flamingos from their so-called sister group (including all descendants of the first group that branches off from flamingos as we trace the flamingo line toward the common trunk of all birds). The sister group of flamingos includes ibises, shoebills, pelicans, storks, and New World vultures—the solution, by sorting analogy from homology, to another old problem by recognizing that New World vultures are storks by homology and carrion-feeding birds of prey only by analogy.

Sibley and Ahlquist have built the evolutionary tree, or phylogeny, of birds by using a molecular technique called DNA-DNA hybridization—a method that can sort homology from analogy. (Molecular phylogeny has been with us for some thirty years, using an astonishing variety of techniques and concepts with varying degrees of success. I choose Sibley's work to illustrate the profession both because I judge his method conceptually superior to all others, for simple reasons explained later, and because Sibley, in his own persistent and hyperenergetic way, has, for the first time, built the complete tree for a major group—and not merely chosen a few uncontested creatures as a pilot demonstration.)

DNA-DNA hybridization is beautifully simple in concept (but quite difficult in detail and application—a fascinating story in its own right, but one that will have to wait for another time if you want to read anything else in this issue of the magazine). DNA, as everyone knows by now, is a double helix made of two strands, each twisted around the other. Most people also know that DNA contains multiple copies (hundreds of thousands in some cases) of many genes (segments of DNA), not just a single copy of each. Sibley's method takes one copy of as many genes as possible and then makes a kind of "brute force" comparison between two species by matching all the DNA that includes a single example of each gene (so-called single-copy DNA). (Since genes may evolve at different rates, we must exclude multiple-copy DNA. Suppose that a species' DNA contains 100,000 copies of a rapidly evolving gene. These repeated sequences will swamp several thousand single-copy genes evolving at average rates and will overestimate the phylogenetic difference between two species. Since we don't know which genes evolve rapidly, slowly, or at average rates, our best estimate will use the brute force method of securing one copy for each gene and trusting—and testing—that positive and negative deviations from average rates will balance in the total wash.)

Sibley and Ahlquist therefore separate out the single-copy DNA and discard the multiple copies. They then dissociate the two strands of the double helix (both steps are easy to say and hard to do). They now have single-stranded DNA containing one copy of each gene. They take the single strands of two species and mix them together. In DNA, as in so much of life, like has an affinity for like. The corresponding parts of the two strands therefore join as best they can, forming a double helix (a so-called heteroduplex) with one strand from the first species and the second strand from another species. The technique then hinges upon a simple chemical fact: The closer the similarity of the DNA from the two species, the tighter the two strands of the heteroduplex will bind, and the greater the energy needed to dissociate them. Binding will be tightest of all for the homoduplex—when both strands come from the same species—and progressively weaker as the DNA strands become more dissimilar. The weaker the binding, the lower the temperature for dissociation. Evolutionary affinity is a simple linear function of heat needed to separate the strands—the lower the temperature, the more distant the relationship.

Why does this method give us an accurate evolutionary tree of branching relationships, and why have the classical data of morphology, physiology, and behavior often failed in detail? Many people suppose, quite incorrectly, that molecular phylogenies work because genes are more real, more basic, more fundamental than the form and behavior of whole animals. We must, in general, struggle against this bad intellectual habit of reductionism and its assumption that proper explanations can only emerge from breaking things into their smallest constituent parts; wholes have as much reality and importance as their building blocks. But we needn't wax so abstract in this case—for DNA wins as a criterion of phylogeny for a specific reason divorced from its status as a molecular code, and not on general principles.

The decoding of phylogeny requires no more than a method for recognizing homology and eliminating analogy. Biologists have long realized that complexity offers the best guide to homology. When similarities between two species are sufficiently widespread and intricate—that is, composed of many hundred utterly unrelated, complex parts—they cannot arise by independent evolution; they must record the passive inheritance of shared descent. Analogous similarity produces uncanny likeness—just consider the marsupial moles, dogs, and mice of Australia—but its results can extend only so far. Natural selection may converge from different directions upon the mechnical optima of certain life styles (thus producing a striking outward similarity in swimming machines, whether they be fish, squid, or mammal), but it cannot undo the homologous handiwork of ages and so restructure an organism that its ties to history are forever lost in current adaptations. If we can look at enough independent details, we will always find homology intact.

Morphology may be our first (and usually adequate) guide, but it just doesn't provide enough independent detail for sorting homology from analogy in difficult cases. Morphology looks complex and multifaceted, but parts do not always maintain their apparent independence. Growth and development link the features of organisms into complex webs of correlation; small changes may trigger cascading effects throughout the body. Similarities that look too complex for analogy may actually arise as consequences of single changes in these triggers. Morphology also acts as the primary breeding ground of analogy, as natural selection guides different lineages to the same optima for similar roles in common environments.

DNA differs from morphology in just those properties that capture homology. DNA is complex enough to preclude analogy as a cause of overall similarity. The items (genes) of a DNA code are also sufficiently independent to guarantee that no simple trigger can engender a large set of apparently intricate similarities. Each gene contains hundreds of nucleotides, each capable of separate change in evolu-

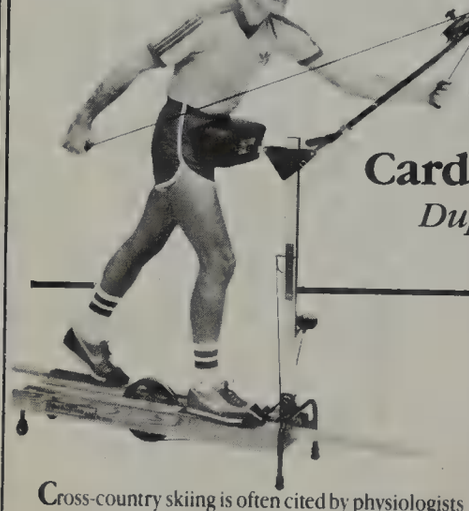
SAAB

The most intelligent car ever built.

Better than Jogging, Swimming, or Cycling...



NordicTrack

Jarless Total Body

Cardiovascular Exerciser

Duplicates X-C Skiing for the Best Motion in Fitness

Cross-country skiing is often cited by physiologists as the most perfect form of cardiovascular exercise for both men and women. Its smooth, fluid, total body motion uniformly exercises more muscles so higher heart rates seem easier to attain than when jogging or cycling. NordicTrack closely simulates the pleasant X-C skiing motion and provides the same cardiovascular endurance-building benefits–right in the convenience of your home, year 'round. Eliminates the usual barriers of time, weather, chance of injury, etc. Also highly effective for weight control.

More Complete Than Running

NordicTrack gives you a more complete work out–conditions both upper body and lower body muscles at the same time. Fluid, jarless motion does not cause joint or back problems.

More Effective Than Exercise Bikes

NordicTrack's stand-up skiing motion more uniformly exercises the large leg muscles and also adds important upper body exercise. Higher pulse rates, necessary for building fitness, seem easier to attain because the work is shared by more muscle mass.

Even Better Than Swimming

NordicTrack more effectively exercises the largest muscles in the body, those located in the legs and buttocks. When swimming, the body is supported by the water, thus preventing these muscles from being effectively exercised. The stand up exercising position on the NordicTrack much more effectively exercises these muscles.

A Proven, High Quality Durable Product

NordicTrack is in its 7th year of production. NordicTrack is quiet, motorless and has separately adjustable arm and leg resistances. We manufacture and sell direct. Two year warrantee, 30 day trial period with return privilege.

Folds and stands on end to require only 15" x 17" storage space.

tion. Such a long string of independen items cannot evolve detailed similarit from initial disparity. A high percentag of item-by-item match in the DNA of tw species must represent homology an shared descent. Sibley and Ahlquist' method of DNA-DNA hybridizatio measures just this matching and uses th largest possible sample size—all single copy DNA. A morphologist may conside hundreds of correlated items. Sibley mea sures millions of independent bits. Thus Sibley's method works for two reasons o mathematical probability, not by any gen eral superiority of DNA over morphology his matches are too complex to evolve in dependently, and his sample size (al nucleotides of all single-copy DNA) is so staggeringly large that any superficia analogy must be swamped by similarity o shared descent.

Such a brute force method possesses a kind of ironic elegance that may even permit us to date the events of phylogeny, not merely to state their relative sequence. In one sense, no technique of molecular phylogeny could be more crude than Sibley's—he simply dumps all the single-copy DNA of two species into his black box and then heats it up. His result, in each case, is just a number—the temperature of dissociation for strands of the heteroduplex. But we live in an age of great sophistication. We could in principle, although it would take forever and cost the world, state the actual basis, nucleotide by nucleotide, of all differences for any number of genes in two species. Why not work with these direct molecular details; why, instead, should we use such a simple surrogate measure—the temperature of dissociation?

To place time on the branches of an evolutionary tree, we need a clock—some measure of evolutionary change that ticks at a constant rate (or at a variable rate that we can calibrate). Genes evolve at different rates. But a measure of change in all genes at once might provide a kind of global average relatively invariant from group to group. Sibley claims that the clock for entire genomes beats with impressive constancy. If a few branching points can then be dated with independent evidence from fossils and geographic distribution, the clock can be set. If the clock beats regularly, all other branching points on the tree obtain a definite date. The determination of forty-eight million years for separation of flamingos and storks relies upon this calibration, not on direct evidence of fossils.

I am convinced that Sibley and Ahlquist have correctly set the relative sequence of branching on the evolutionary

IT LOOKS AS GOOD AS IT FEELS

There's nothing else quite like the mysterious beauty of dancing flames. Fireplaces have always been a source of fascination as well as warmth.

Now you can create a designer atmosphere with a Ceramic Hearth Classic® by WESO. Choose from 8 styles and 7 colors. A Ceramic Hearth Classic is 6 times more efficient than a fireplace and is practically self-tending. It circulates a warm, gentle heat throughout the room in a way no open fireplace can match.

Write today to find out more about this uniquely beautiful and practical concept. It's designed for you.

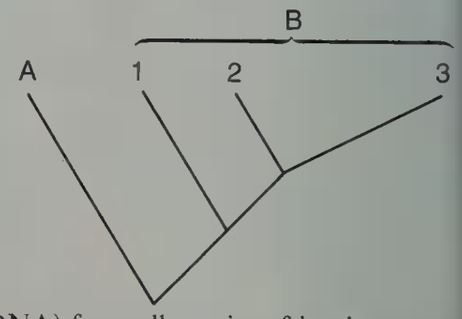
tree of birds—the essence of phylogeny. I am more skeptical about their claims for clocklike precision (neither convinced nor in any way opposed; just waiting for more data from other groups of organisms). In any case, Sibley's claim for "uniform average rate" of evolution in single-copy DNA can be tested in a straightforward way. The hypothesis of uniformity predicts that any species (A in my diagram) will be equally distant (as measured by



DNA) from all species of its sister group (B) because A shares the same branching point with all species of B. Opponents of constancy predict that since some species in B diverged faster and farther than others from the common ancestral state (morphology certainly records these different degrees of departure), A will be closer to some species in B than to others as measured by DNA. (Call A an orangutan, B_1 a gorilla, B_2 a chimp, and B_3 a human, and you will see the point. By Sibley's clock, orangs should be equally distant from gorillas, chimps, and humans; opponents might expect a greater distance between humans and orangs.) Limited testing so far must give the advantage to Sibley. I hope that he is correct.

We should all rejoice in the success of molecular phylogeny because its techniques have probably solved *the* biological problem of the ages, so recognized ever since Aristotle (and surely, in unrecorded form, well before—whenever people puzzled about their place in nature): namely, how, and why, are organisms interrelated? And how do we, so topheavy and physically defenseless, fit into the general scheme? Monkeys fascinate us because we perceive affinity in our guts; carrots evoke no sympathy, even from the kindest of vegetarians, because they don't look and work enough like us.

No other issue has so consumed the attention of naturalists throughout human history and across cultures. Darwin solved the "first-order" problem by showing that a simple history of physical descent, not the inherent and timeless plans of a creator, had forged the pattern of relationships among organisms. Darwin answered the *why*, but not the *how*. He taught us the reasons for similarity; he did not (and could not) specify the actual map of rela-

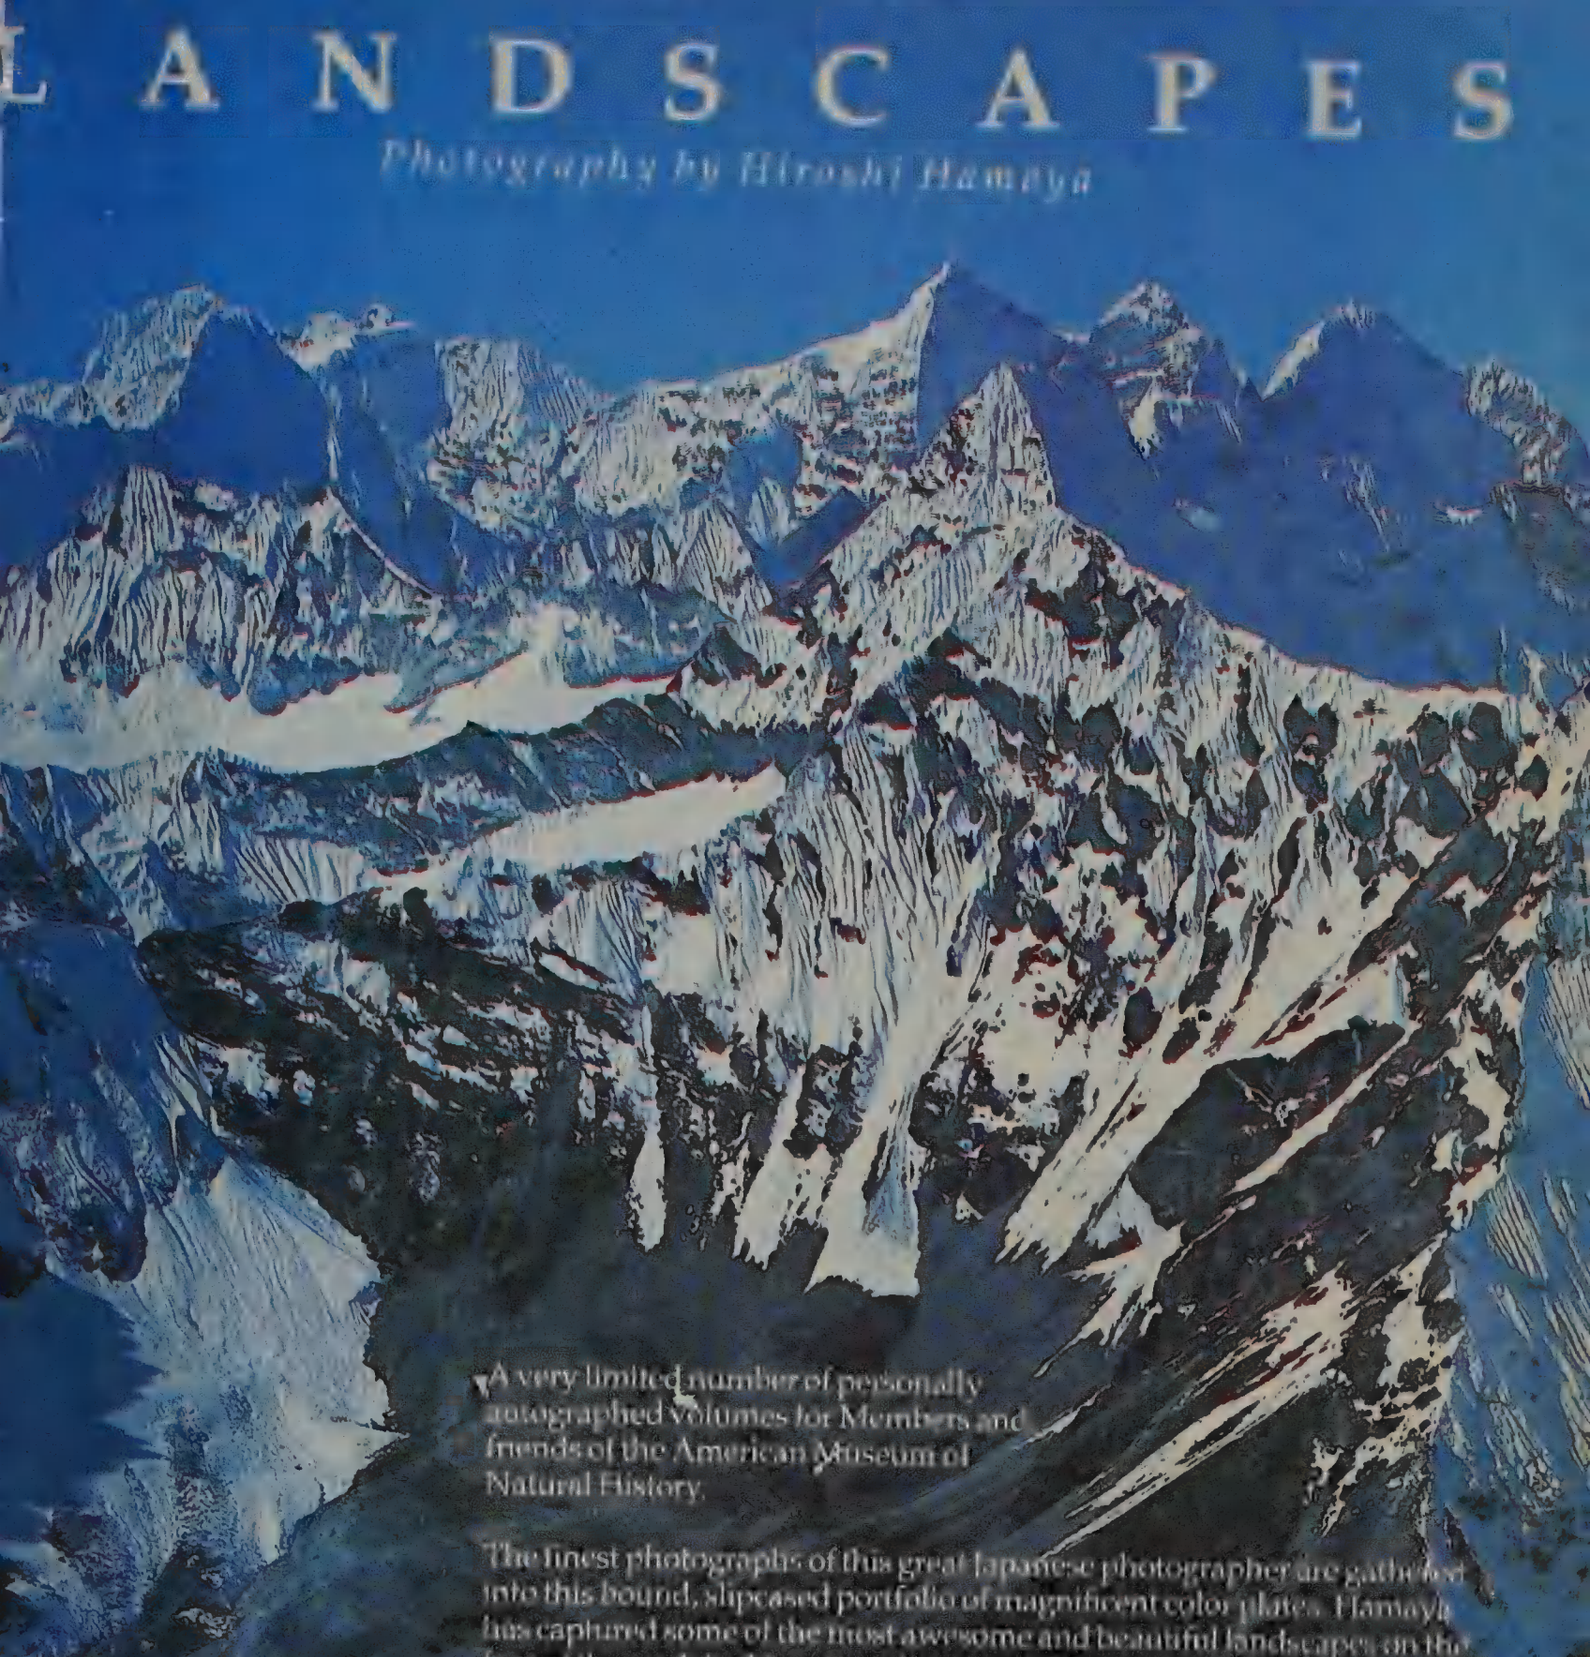
Photography by Hiroshi Hamaya



A very limited number of personally autographed volumes for Members and Friends of the American Museum of Natural History.

The finest photographs of this great Japanese photographer are gathered into this bound, slipcased portfolio of magnificent color plates. Hamaya has captured some of the most awesome and beautiful landscapes on the face of the earth in this extraordinary portfolio.

Each volume is hand-signed by Hamaya in Japanese and English, and carries his personal character seal.

"As an accomplishment in color printing, book craft, and quality . . . this volume is at a level rarely reached by photography books. As an artistic and philosophical statement, Hamaya's book is a resounding affirmation that the earth possesses a majesty nearly beyond description." —Owen Edwards, Executive Editor of *American Photographer*

To order, please send name and address with a check for $130, made out to the American Museum of Natural History (delivery and insurance included). If you prefer, you may call our toll free number (800) 247-5470; please have your Visa or MasterCard ready. The volume may be returned for a full refund if not completely satisfied.

STIFF UPPER LIP, AND ALL THAT.

Englishmen live imperturbably with their relentlessly wet weather. But they also invented the trench coat and the rolled umbrella. And get along just swimmingly.

Unflappable Englishmen still dress for dinner in climates so sweltering that the idea seems self-punishing. But by savoring a tall, iced Beefeater® and tonic, they manage to keep their cool.

The English, you see, believe in keeping a stiff upper lip in the face of adversity. But they're equally good at keeping adversity to a manageable level. Which probably explains why they invented the trench coat, the rolled umbrella, and the Beefeater Gin and tonic.

BEEFEATER® GIN.
The Crown Jewel of England.™

IMPORTED FROM ENGLAND BY KOBRAND CORP. NY. NY 94 PROOF 100% GRAIN NEUTRAL SPIRITS.

THE SPECIAL DELIVERY GIN.

To begin with, Beefeater® Gin is distilled, bottled and sealed right in the distillery in London—the only gin you can buy which is so protected.

The individual number on the back label identifies the stillman who distilled your bottle of Beefeater®.

It's like the return address on the back of a personal letter.

Notice the little notches on the label. They tell you to whom your bottle was shipped. We almost literally shepherd your bottle right to your door.

And if you think the delivery is special, wait till you taste the gin.

tionships—the problem of phylogeny. T classical data of morphology provided outline for such a map (and had done long before Darwin), but could not sup all the details because (for reasons pr ously discussed) morphology sometim includes such an inextricable hodgepo of homology and analogy.

If molecular phylogeny has been p sued for nearly thirty years, why do I p claim its success now? Previous stud have usually taken a few widely scatte forms—*the* goat, *the* dog, *the* monk and other maddening and meaningless stractions of biological richness—a drawn a phylogeny affirming what eve one already knows. But natural histori dwell with God in the details. We want allocate our problematical groups (l flamingos), not simply stroke our e with molecular affirmations that mous to rat as sheep is to goat. We want a co plete phylogeny for groups that pique interest, not a simple ordering for a f unambiguous branch tips.

Birds are among the best known and haustively compiled of all biologi groups. Their roster of 9,021 species probably not increase greatly. But wh we know the species of birds, our attem to hook them all up into a comprehens phylogeny have been consistently fr trated by more than the usual number "flamingos"—difficult groups that c flate homology and analogy beyond point of morphological resolution. Sib and Ahlquist have worked for more tha decade to produce the first exhaustive m lecular phylogeny for all families in a m jor group. They have now run 1,600 s cies and managed to place all but 3 of 171 families of birds on their chart.

Sibley and Ahlquist's phylogeny is only complete but also interesting. achieves that lovely optimal level of sci tific originality—conservative enough win our allegiance but replete with s prises to spark our fascination. Again a again, it makes sense (in satisfying, of unorthodox, ways) of situations that m phology had muddled or made distre ingly complex. Consider two exampl one a pleasing affirmation of what shou be so (but morphology had questione the other a surprising but beautifully s sible resolution of an old dilemma.

1. *The case of the ratites.* South Hemisphere continents feature la flightless birds called ratites—rheas South America, ostriches in Africa, wis, cassowaries, and emus in the gion of Australia and New Zealan Since all these continents were or united as Gondwanaland, the curre

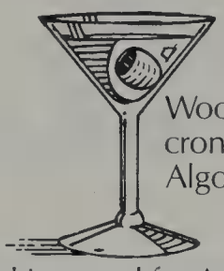
separation of flightless birds records geological history, and the phylogenetic relationship of all ratites has not been seriously questioned in recent years. But morphology raised a dilemma of detail—a potential discordance of phylogeny and geography. Some (but by no means all) experts working with morphology argued that Australian emus and cassowaries are most closely related to geographically distant ostriches and rheas and not to the neighboring New Zealand moas and kiwis. But Sibley and Ahlquist's DNA phylogeny accords perfectly with geography: cassowaries, emus, and kiwis (the extinct moas provide no DNA) form a closely knit subgroup within the ratites; they join the ostrich-rhea group at substantially greater phyletic distance.

The case of the Australian songbirds. If God favors beetles among insects because he made so many of them (as the old quip goes), then surely he loves songbirds among our feathered friends. Of 9,021 species of birds, 58 percent (or 5,274) belong to the Passeriformes, or songbirds. The Australian region contains a fair chunk of this radiation—more than 700 species of respectable antiquity, excluding recent immigrants.

As everyone knows, Australia's native mammals tell an evolutionary story well tuned to their geographic status. Australia, though once tied to other Gondwana continents, has been a separate island for several tens of millions of years. The native mammals, nearly all marsupials, have evolved entirely on their own, radiating into roles and niches filled by placental mammals on other continents. Some, like the koala and kangaroo, have discovered morphologies unknown elsewhere. Others have evolved some of nature's most stunning and complex analogies by converging on the common forms of Northern Hemisphere placentals—Australia, for example, sports its marsupial versions of "mouse," "mole," and "dog." But morphology, in this case, does not fail us. All the intricate analogs have retained their basic marsupial signature—the pouch, the epipubic bones, and a host of other features that identify their homologies.

But the songbirds, as traditionally interpreted, tell a different story that makes less sense (geographically speaking) and that requires special pleading to harmonize with Australia's geological history. The Australian passerines include several groups so similar to well-known birds of other continents that classifications have

"I MUST GET OUT OF THESE WET CLOTHES AND INTO A DRY MARTINI."



So exclaimed Alexander Woollcott one rainy day to his cronies at the famous old Algonquin Round Table.

Woollcott was not alone among the literary lions in his regard for America's favorite cocktail.

Somerset Maugham and Alex Waugh were both avowed martini men.

But none, including Woollcott, was really inclined to save his martini for a rainy day.

After all, New York has been known to go weeks without rain.

generally allocated the Australian species to the broad taxa of their look-alikes living elsewhere. The Australian fairy wrens (Maluridae) and Australian warblers (Acanthizidae) have been allied with true warblers (the Afro-Eurasian Sylviidae) in traditional classifications. *Drymodes*, the Australian scrub robin, looks like an Old World thrush, down to details of bone lengths and bill proportions. *Daphoenositta* looks and lives like a nuthatch; its taxonomic position has remained something of a mystery but, if only *faute de mieux*, ornithologists generally place it adjacent to the true nuthatches in their classifications. The monarch flycatchers of Australia generally occupy a taxonomic position next to the true flycatchers of other continents, and one genus of Australian robins (*Microeca*) looks so much like an Old World flycatcher that Ernst Mayr, our greatest living ornithologist, once considered (as he confessed to me) placing them in the same genus as European forms.

If these taxonomic placements are correct (by recording homology), then we are forced into an improbable zoogeographic hypothesis. Warblers, thrushes, flycatchers, and nuthatches are distinct groups, long separate. If Australia really harbors a few representatives of each, then they must have arrived in several separate waves of colonization—and such a theory of multiple invasion has been the traditional (and uncomfortable) view. But why should mammals and birds tell such different stories? Why should Australia's mammals form a coherent group with remarkable convergences upon foreign placentals, and its birds be an unrelated hodgepodge of so many separate invasions? Yes, I know—birds fly and mammals don't. Still, most birds are not as mobile as their metaphorical status implies—and Australia has resided thousands of miles from anywhere else for a long time.

Sibley has just completed his DNA phylogeny for the oscine passerines (or true songbirds), including all these Australian forms—and, as he told me on the phone last week, he received the greatest surprise of his decade's labor. By DNA homologies, the oscines break into two major groups, separated by fifty-eight to sixty million years: the Muscicapae, including thrushes, swallows, starlings, warblers, larks, sparrows, and finches; and the Corvi, including most prominent songbirds of the Australian region (lyrebirds, bowerbirds, fantails, drongos, birds-of-paradise) and also crows, ravens, magpies, jays, orioles, shrikes, and vireos. The geographic concordances are simple, elegant, and convincing. The Corvi diversified in the Australian region, the Muscicapae elsewhere. (This discovery, by the way, will bring much joy to patriotic friends down under, for it forces a reinterpretation of Australia as active supplier, not only as passive recipient of superior forms evolved elsewhere [as the wipeout of so many marsupials by introduced placentals has encouraged]. The crow subgroup "escaped" from Australia to Asia, probably some twenty to thirty million years ago, and evolved there to its current diversity. But Australia, as Sibley writes, "was the nursery of the Corvi.")

Sibley's phylogeny beautifully resolves, in one swoop, all the old dilemmas listed above. The Australian "wrens," "warblers," "robins," "nuthatches," and "flycatchers" had been placed with their look-alikes in the Muscicapae—the great non-Australian branch of the songbirds. Every last one of these troubling species belongs, by DNA homologies, in the Corvi—the other great branch that evolved in Australia. We need no special pleading, no multiple migrations from impossible distances. The morphological similarities to members of the Muscicapae are analogies, not homologies.

The Australian songbirds, in other words, tell the same tale as the marsupi-

BIRD'S-EYE VIEW

Designed in collaboration with internationally famous ornithologists, Swift's Audubon and Osprey binoculars give you a superior combination of performance and durability.

OSPREY MK. II weather-protected binocular

The 8.5x,44 AUDUBON Wide Angle is tops in the field — with an extra-wide field of view (445 feet), crisp close focusing to 13 feet, and hairline definition.

The 7.5x,42 OSPREY is distinguished by its rubber armor protection and slip-on rainguard that eliminate the need for a cumbersome case and allow it to be used safely in virtually any weather conditions. Close focusing to 13 feet.

For technical excellence and enduring quality, Swift binoculars are the natural choice.

Presenting...in the Great Tradition of Classic Bronze Sculpture

"The Wicked Pony"

By Frederic Remington

Issued in a single, Limited Edition of 9500 serially numbered sculptures.

Shown smaller than approximate size of 9" high.

- **Painstakingly hand-finished and hand-rubbed to the rich patina of classic bronze.**
- **Hallmarked, registered, and individually serially numbered. Certificate of Registration.**
- **Priced at just $195.00.**

Frederic Remington's powerful masterpiece of bronze sculpture, "The Wicked Pony," brilliantly captures a dramatic battle of wills between horse and rider. Flourishing his technical virtuosity — note the balance and symmetry of the bucking pony — Remington created "The Wicked Pony" from a real life incident. This spectacular work of art is unique among Remington's sculptures as the only one where the horse triumphs over man.

And now, the New England Collectors Society is proud to announce the issue of "The Wicked Pony" by Frederic Remington in a magnificently crafted, one-third size, museum quality reproduction of cold-cast bronze. This exclusive Limited Edition has been created under the direct supervision of Ms. Christine Roussel, former Director of the Reproduction Studio of the Metropolitan Museum of Art, and advisor to the Rockefeller Collection.

Each individually serially numbered "Wicked Pony" in the Limited Edition of only 9500 sculptures will be individually cast of cold-cast bronze, a modern sculpting medium which holds even finer detail than traditional hot-casting. It will then be hand-finished and hand-rubbed to a classic patina.

Each "Wicked Pony" is also hallmarked, registered and accompanied by a Certificate of Registration. It is an impressive work of art and a rewarding acquisition that will surely be treasured for generations.

To reserve your "Wicked Pony" simply complete and return the reservation application. No money need accompany your order at this time.

–phylogenetic coherence in geo-
ohic isolation with rampant conver-
ce upon groups that inhabit the rest of
world. Marsupials retained morpho-
cal signatures of their homologies; the
stralian passerines either failed to sign
vrote in an ink as yet invisible. If it can
erate such sensible conclusions, Sibley
Ahlquist's method must be right (this
gut feeling, not a logical argument).
Lord may be subtle, to recycle an Ein-
n quote of two columns ago, but he is
perverse.

We should all care deeply about
ley's conclusions, for his sensible reas-
ments by homology reinforce the most
portant theme that evolutionary theory
taught us—the overwhelming pre-
ninance of history as the cause of na-
e's ordering. Convergence (or similar-
by analogy) can be, in Sibley's words to
, "subtle as subtle can be," yet analogy
not overwhelm the likenesses im-
nted by history and descent into the
gest taxonomic sample of all—the sin-
-copy DNA of any species. But history
ws along constrained pathways of form.
e optimal solutions for form in certain
vironments act, one might almost say,
a set of timeless Platonic types. Wren-
ss, dogness, and wormness are formal
mes that transcend time, and nature's
otoplasm flows through them again and
ain. Life becomes a fascinating and
mplex interplay of these opposing con-
otions: the homology of history and the
alogy of optimal form; dynamism and
ucture; motion and inherence; unique-
ss and repetition.

Sibley's work, and other efforts of mo-
ular phylogeny, have received a fair
g of press lately, but I do not fully un-
rstand why we are not proclaiming the
ssage from the housetops. Biology and
mmon culture have struggled to portray
e relationships of organisms for thou-
nds of years. We finally have a method
at can sort homology from analogy. The
swer oozed up on us over many years; it
so emerged from a profession with low
blic recognition and no designated No-
l Prize, so most outsiders to the club
ven't noticed. Perhaps we should mount
e parapets and shout: "The problem of
ylogeny has been solved." But then we
ust descend and get to work—for the so-
tion is only a beginning, a calibration
d context for all the interesting ques-
ons. For starters, would you believe (as
bley now claims) that chimps are closer
humans than to gorillas?

*Stephen Jay Gould teaches biology, geol-
gy, and the history of science at Harvard
niversity.*

The dynamic range of the Toshiba V-S46 is a window rattling, speaker-blowing 80 dB. And there's much more to it than meets the ear. Such as four video heads for snow-free slow mo and freeze frame. A 20-function wireless remote. Plus front loading and 117 cable channels. Turn it up and you'll either want to buy a new pair of speakers. Or have to.

The Prince and the Painter

by Stephen J. Pyne

KARL BODMER'S AMERICA, Introduction by William H. Goetzmann, Annotations by David C. Hunt and Marsha V. Gallagher, Artist's Biography by William J. Orr. *Joslyn Art Museum and the University of Nebraska Press, $65.00; 376 pp., illus.*

In frontier days, appreciation for the American Indian increased with distance. On the frontier itself, the Indian was considered a nuisance. Farther east, especially in centers of learning and natural history, he was sometimes an intellectual puzzle. In Europe, he became an ethnographic marvel. America's West was also Europe's, and the important images and information about the West were as much a product of European high culture as of the experience of frontiersmen.

Thus in the 1830s, when artists went West to paint the Indian, two were Americans from the East (George Catlin, Alfred Miller), and two of the three major expeditions had European sponsors—William Drummond Stewart, an adventurous Scottish baronet, and Prince Maximilian of Wied-Neuwied, a German devotee of natural history. Maximilian's expedition had the strongest intellectual component, yet its most stunning legacy was the meticulous portfolio of its young Swiss artist, Karl Bodmer. The purpose of Catlin's photographs was to record, and they were often hastily done and suggestive rather than definitive; Miller's watercolors, in contrast, were lyrical rather than documentary, evoking a preadamic state of nature. But Bodmer's work combined the hard edge of science with a Romantic delight in the wild, the natural, and the picturesque.

That Bodmer painted the Indians of America was something of an accident. Inspired by Alexander von Humboldt, Prince Maximilian had previously traveled to Brazil (1815–16), where he explored jungles and assembled natural history collections. His published account featured his own drawings, and friends tactfully suggested he engage a professional artist for his next journey. Bodmer had just illustrated a travel book on the Moselle Valley; it caught the attention of Heinrich Schinz, a Swiss naturalist, who recommended Bodmer to Maximilian. After some haggling, Maximilian and Bodmer came to terms, and on May 17, 1832, they set sail for America to collect specimens from the West and to study th "aboriginal nations of America."

Bodmer and Maximilian spent a yea dodging cholera epidemics, but visited th major centers of learning for natural hi tory (among which Philadelphia was mos prominent), conversed with American sa vants, and spent nearly five months a New Harmony, Indiana, recuperatin from illness, doing research in the large l brary, and discussing science with th town's prominent naturalists. Bodme made a brief excursion to New Orlean and back. Finally, in the spring of 1833 the party traveled by steamboat and keel

A Stop; Evening Bivouac

The InterNorth Art Foundation/Joslyn Art Museum, Omaha

boat up the Missouri River fur trade route to Fort McKenzie. Bodmer painted landscapes and drew animal specimens collected by Maximilian.

At the fort, however, their ethnographic impulses were satisfied. A rumor that being painted by Bodmer made one immune to bullets brought the artist abundant clients, most decked out in full regalia. Avidly he painted Blackfeet, Kutenai, Atsina, and Assiniboins. The contrast between these magnificent people and the demoralized Indians Bodmer had seen near settlements was powerful. Maximilian pondered the mystery of the Indians' origin, quickly seizing on the idea that they had a common ancestry with the tribes he had known in Brazil. Bodmer declined to paint the fur traders and trappers he encountered; this was an ethnographic expedition, not an exercise in portraiture or an indulgence in the picturesque.

Persuaded not to travel south to the Rockies, the small expedition retired to Fort Clark, North Dakota, to spend five cold, wretched, filthy, undernourished—but productive—months among the Man-

ns. Two years later, smallpox virtuly wiped out the tribe. In July 1834, afr a detour to Niagara Falls, Maximilian, odmer, a hunting companion, their specens, and two live bears left New York r Europe. Tragically, most of Maximiln's collections had been destroyed in the nking of a Missouri steamboat. The most nportant record of their travels, however, as Maximilian's detailed diary and odmer's portfolio. Between 1839 and 843, *Travels in the Interior of North merica* was published in French, Gerian, and English, with a supplemental atas consisting of eighty-one aquatint plates om paintings Bodmer composed out of is field sketches.

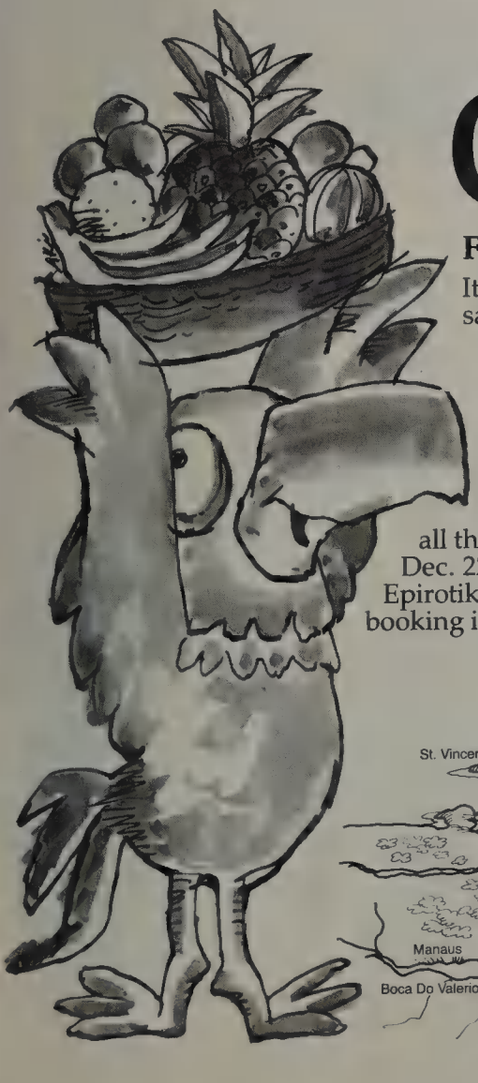
Although the book was a splendid prouction, its expensive price made it a fiancial disaster. Prince Maximilian later lanned, but had to abandon, a journey to entral Asia. Bodmer declined a chance to oin an expedition to Egypt. Exhausted om his labors, he eventually retired to ne artists' colony at Barbizon, France, here he indulged his passion to paint forsts and animals. For a while he achieved ome financial success and critical attenon doing illustrations for periodicals, but n comparison with his North American rt, this work seems insipid and academic. His last years were spent alone—melancholic, sick, out of artistic favor. He and Maximilian continued to correspond.

Bodmer's American travels stood as a unique experience, a magnificent anomaly compared with the work he did before and after it. As an artist he is best known, rightfully, for his wonderful portraits of Indians. Because Bodmer was hired to illustrate a scientific expedition, his art was tempered by that purpose. The resultant sketches and watercolors tend to be uncluttered, unconventional, a bold mixture of hard-edged clarity and delicate detail. The portraits, in particular, stand up both as ethnographic types and as portrayals of individual people. There is nothing sentimental about them. Indeed, the painted faces, animal headdresses, and stoic glares often have a diabolical quality.

The landscapes are more complex and somewhat more conventional. Except for a few scenes on the Missouri where the rock outcrops are reminiscent of Rhine castles, Bodmer's landscapes lack the intensity of his portraits or the calculated frenzy conveyed in his aquatints of Mandan dances or Blackfoot-Assiniboin battles. Perhaps most unsettling are his watercolors of religious sites; Bodmer makes a prairie shrine ringed with buffalo skulls into a Mandan Stonehenge.

Bodmer also painted buffalos, vultures, pronghorns, and sandcranes—all of which have the same qualities that make his Indian portraits so compelling and informative. Apparently it was the synergism of naturalistic realism and Romantic sensibility that gave the portfolio its special quality. Without the science, Bodmer's art lost its power. But for all his extraordinary skill, Bodmer's synthesis was not unique. His pictures are startlingly pure compared with the more traditional academic and museum art of the era, but they are of a piece with a tradition of art in the service of science. Bodmer's portfolio—like Maximilian's expedition—was part of what historian William Goetzmann has termed a Second Great Age of Discovery. They are in the same tradition that inspired the watercolors of William Hodge and the specimen drawings of George Forster—both of whom sailed with Captain Cook in the eighteenth century—and the watercolors of Antarctic penguins and icebergs done by Edward Wilson, the artist-physician with Robert Scott's expedition, in the early twentieth century.

This isn't the first book about Prince Maximilian's travels, and it isn't the only book on Bodmer's art. But it is the only one to include all of Bodmer's American works. The production is well designed and generously executed; the text shim-



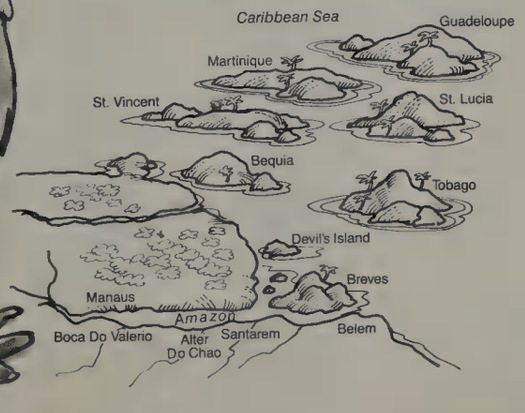
THE CARIBAZON CRUISE

For the price of the Caribbean, Epirotiki also gives you the Amazon.

It's the most successful new cruise in Caribbean history. With a waiting list for each sailing this past winter. Don't be left out in the cold next winter. Our incredible Caribazon combines the height of luxury in the Caribbean with high adventure on the Amazon. You'll call at the choicest tropical islands. Then cruise a thousand miles up the fabled Amazon with its breathtaking fauna and flora, history and legend. With expert lecturers to help you capture every moment.

A Renaissance in the Caribazon.

Our 11-day itinerary will be performed by the world famous World Renaissance. With all the style, marvelous cuisine and great entertainment she's famous for. Cruises begin Dec. 22, 1985 from $2,100 to $3,000 including roundtrip airfare to the ship from Miami. Epirotiki's Caribazon: the Caribbean cruise with the Amazon difference. It's only a question of booking it early enough.



Epirotiki Lines, 551 5th Ave., New York, NY 10176
800-221-2470; in N.Y. (212) 599-1750
Send Caribazon color brochure at once.

EPIROTIKI
A WORLD OF CRUISES.
A WORLD OF DIFFERENCE.

mers with insight. William Goetzmann's introductory essay deftly describes the intellectual context of the expedition, both in the United States and in Europe—the state of knowledge about the West, its natural history, and the Indians who lived there; and the intense ferment in German thought, especially about problems of life and history, that explains much of Maximilian's curiosity. Maximilian emerges as a serious scholar, and not as a dilettantish tourist or a bored noble eager to shoot wild game. Extracted from Prince Maximilian's letters and diaries, the annotations to the plates—written by David Hunt and Marsha Gallagher—are unobtrusive and informative, complementing rather than confronting the reproductions. A biography of Bodmer by William Orr successfully places the American episode in Bodmer's evolution as an artist. Inevitably, there is a good deal of overlap among these three parts of the book as they describe the critical American journey. But each accents the story differently, and the result is an ensemble, not an anthology.

The book pays tribute to Bodmer not only in its message but in its medium. The mixture of affecting detail and bold concepts, the largeness of the book and the lightness of its composition convey the same impression of rigor and feeling that emanate from Bodmer's best work. *Karl Bodmer's America* will become a valuable sourcebook for scholars interested in the West, Indians, and American intellectual history. The expense of the book will discourage casual buyers, but nothing about it should discourage casual readers. Anyone who wishes to learn what the West was like in the early 1830s and how our images of it have come to be forged will find the book a delightful introduction.

Buy a Nikon FG and get something

Even if you've never held a 35mm SLR camera in your life, you'll find everything about the Nikon FG easy to use.

First, with every FG camera and Nikon lens you buy between March 1 and June 30, there's a $25 rebate.* And chances are, you know exactly how to use that.

But don't think mere money is a good enough reason to buy the FG. Think about its versatility.

The FG offers you as much, or as little automation as you want.

In the Programmed mode, anyone can take perfectly exposed pictures from day one. A microcomputer automatically sets the proper aperture and shutter speed.

If you want more creative freedom, the Automatic mode allows you to set the aperture yourself to control depth-of-field. And in the Manual mode, you can make all the settings yourself to control everything.

The FG even has Through-The-Lens flash metering (TTL, for short). Along with the optional Nikon SB-15 Speedlight, it makes it simple to take even the most complex flash pictures.

11-049395

The Redheaded Newcomer

adicchio, an Italian immigrant,
as achieved a special status in America

Raymond Sokolov

Everyone has had the experience of rning a new word and then coming ross it over and over again immediately erward. But how often does this happen th a new vegetable?

In the late fall of 1978, in Vienna, I first countered a dark red salad "green" with attractively bitter taste. Moving southward into Italy, I kept seeing heads of this red "lettuce" everywhere. Italians called it *radicchio*. Upon returning to New York, I began seeing it in supermarkets, where it sold for a small fortune.

The process by which this distinctively colored and flavored traditional winter green of the Venice region achieved its current status as the very signpost of chic dining in advanced American restaurants is not recorded. But it happened very rapidly, as part of the general hunger for dramatically exotic foods inspired by the *nouvelle cuisine*. A computer search of the *New York Times* shows how quickly radicchio ceased to be a mysterious oddity

Three recipes adapted from *Pasta and Rice, Italian Style* by Efrem Funghi Calingaert and Jacquelyn Days Serwer (Charles Scribner's Sons)

Radicchio alla Griglia

(Grilled Radicchio)

- 2 medium heads radicchio
- ½ cup olive oil
- Salt and freshly ground pepper

1. Preheat broiler.
2. Remove and discard hard outer leaves. Cut each head vertically into 4 pieces, and wash well in cold water. Shake vigorously and pat dry with paper towel.
3. Put pieces on a dish, drizzle with olive oil, and sprinkle with salt and pepper.
4. Place the pieces on a rack and run them under the broiler for 3 to 4 minutes on each side. Grilled radicchio is equally good served cold.

Yield: 4 servings

Risotto with Grilled Radicchio

- 2 heads radicchio, grilled (see recipe above)
- 5–6 cups meat stock
- 6 tablespoons butter
- 1 small onion, minced
- 2 cups Italian arborio rice (or Carolina long-grain rice)
- ⅓ cup Cognac
- ¾ cup freshly grated Parmesan cheese

1. Chop the grilled radicchio crosswise into small pieces.
2. Bring the stock to a boil, then reduce heat so that it simmers gently.
3. Melt 2 tablespoons butter in a heavy-bottomed saucepan over medium heat. When the foam subsides, add the onion and sauté until translucent. Then add the radicchio and sauté for 2 to 3 minutes more.
4. Add the rice, raise the heat to medium-high, and sauté for 1 to 2 minutes longer, stirring vigorously. Add the Cognac, stir, and let evaporate. Then begin adding the broth a cup at a time, over medium heat. Stir well around the sides and bottom until the liquid is absorbed but the rice is not completely dry. Keep adding broth and stirring in this way. The consistency should always be creamy. Depending on the rice, it will take from 18 to 25 minutes to cook. Near the end it is advisable to add the liquid cautiously, since the rice will absorb it more readily when almost done. If you run out of broth, simply add hot water. The risotto is done when it is *al dente*, tender but firm. The sauce should be creamy, not runny. Just before the rice is done, add cheese and remaining butter. Stir well and taste for salt. Turn heat off, cover, and let rest 1 to 2 minutes. Then serve in a heated dish.

Yield: 4 servings

Penne al Radicchio

(Quill-shaped Macaroni with Radicchio)

- 3 tablespoons butter
- 1 medium onion, minced
- 3 tablespoons vegetable oil
- 1 pound radicchio, washed and cut into half-inch pieces
- Salt and freshly ground black pepper
- ½ cup dry white wine
- 8 ripe plum tomatoes, peeled and puréed, or 8 canned Italian tomatoes, puréed
- 1 cup heavy cream
- 1 pound penne (or similar pasta)
- ¾ cup freshly grated Parmesan cheese

1. Heat the butter in a large skillet and sauté the onion until translucent.
2. Add the oil, the radicchio, salt, and pepper. Stir well. Cook for 5 minutes. Add the wine, stir, and cook until evaporated. Add the tomato and 2 cups water. Bring to a boil, reduce heat, and simmer for 45 minutes, stirring from time to time. If the sauce gets too dry, add a little water.
3. Add the cream to the sauce, stir, and simmer for another 10 minutes.
4. Meanwhile, bring 4 to 5 quarts of water to a boil in a large pot. Salt lightly and drop in the penne or other pasta.
5. Start testing the penne for doneness after 8 minutes or so. Drain in a colander when the pasta is *al dente*, still a bit chewy but neither tough nor limp.
6. Toss the sauce and the pasta together in a heated bowl or other serving dish. Add the Parmesan cheese. Toss. Taste for salt. Serve immediately.

Yield: 4 servings

l Solomon; Wheeler Pictures

and turned into just another familiar feature of gastronomic chic.

On April 19, 1981, a reader's query to the garden page asking for a source for radicchio seeds drew a blank from "Garden News." But by May 3, the newspaper of record had recouped. Alert readers had supplied two sources for "the hard-to-find seed of Italian red chicory, radicchio," which was also identified in the same paragraph as "red verone."

This clarification led to more confusion. Red verone was a half-baked version of the French name for radicchio, emanating from the French seed company, J.A. Demonchaux, of Topeka, Kansas, which was one of the two suppliers mentioned in the article. Then there was the business of calling radicchio "chicory."

Perhaps gardeners were not confused by this identification. Well-grounded Linnaeans would have known that the true chicory, *Cichorium intybus*, is what supermarkets and most of the rest of us call endive (also Belgian endive, or witloof). This expensive blanched product is usually produced in Belgium. The white, boat-shaped leaves, called *chicons*, grow on parsniplike roots that are marginally edible but most commonly employed as an admixture to coffee. In the mid-nineteenth century, someone noticed that chicory root left in the dark produces white leaves. The head horticulturist at the Brussels Botanical Gardens, a certain M. Brezier, perfected the new vegetable. The first box was imported to the United States in 1911.

Weed-conscious Americans also know true chicory in a wild form that produces appealing blue flowers alongside roads. We have had these weeds since the last century, but I don't recommend trying to grow Belgian endive from their seed.

You certainly shouldn't try to use their seeds to grow true endive, *Cichorium endivia*, which may belong to the same genus as chicory but is quite different. American markets sell its green leaves as chicory and escarole. The scientific names for these two species of *Cichorium* are confusing in themselves, since *intybus* and *endivia* are actually both reflexes of a Greek word meaning, you guessed it, endive or chicory. And since the art of plant description in ancient days was primitive, it is impossible to tell if the ancestor words for chicory and endive were meant to refer to different plants in a consistent way or were used redundantly.

Today, even with binomial names and a relatively stable horticultural situation, confusion is the word on the *Cichorium* front. Endive is a chicory, chicory is an endive, and radicchio . . . well, according the *New York Times* food advice colum of April 27, 1983, radicchio is a "wi form of chicory most commonly assoc ated with the Veneto region of Italy."

There is some truth in the above, fa more than in the contradictory and incon plete information the newspaper had ea lier printed on radicchio culture. Radi chio is a true chicory (the same species a Belgian endive). But it certainly isn't wil Only careful treatment will encourage th roots to produce those red leaves that hav made the plant an international superst This is not the place nor am I the fellow t advise you specifically about the appropr ate methodology for growing one's ow radicchio in, say, the New York metropo itan area. A great deal seems to depend o climate. But the classic method generall begins with a midsummer planting. Be fore winter, radicchio grows a first crop o mild green leaves suitable for salad. Afte these are cut back, if the roots are kep warm—but not so warm and humid tha they rot—cold weather will promote th appearance of a second crop, this time o red leaves.

The radicchio we tend to see in our mar kets comes in tightly "hearted" heads This is the traditional radicchio variety o Castelfranco, a town in the Veneto regio

You have the freedom to turn the unexpected corner. Such is your Royal advantage on Royal Viking Line! We've just carved out a new jewel in Asia, from Siam to Bali, and invite you to cruise with us in the warm, clear light of autumn with your choice of two rare 13-day itineraries. And a free land package in Hong Kong or Singapore before or after your cruise.

Depart October 21 or November 16 for ancient Siam and the exotic mood of Malaysia; Zhanjiang, China; Phuket, and Langkawi Islands, and an overnight in Bangkok.

Sail November 3 or 29 for colorful Jakarta; Zamboanga and Cebu in the Philippines, with overnight stays in fabled Bali and Manila.

Or combine both itineraries and receive free air fare.

Do hurry and book. Royalty waits for no one!

ROYAL VIKING LINE
World Wide cruising. World Class style.

51BNH04

Bali, Indonesia

ere the great Renaissance painter Gior-
ne was born. In nearby Treviso, there is
ifferent variety that does not heart, but
oduces long, straight leaves, somewhat
e Romaine lettuce, with white, celery-
e stalks and ruby red, white-veined
ves.

Sometimes, the two varieties are mixed
make a so-called Treviso salad, but if we
to believe the late food historian
averley Root, the two are never mixed
Treviso. Trevisan radicchio is so prized
Treviso that, before Christmas, it has its
n market in the loggia of the Palazzo
i Trecento. And the plant has its own
k jingle:

Se lo guardi, egli è un sorriso
Se lo mangi è un paradiso
Il radicchio di Treviso.

To look at, it's quite nice
To eat, it's paradise
The radicchio of Treviso.

All in all, this is a good description of an
tremely attractive leaf vegetable. For
e gardener, radicchio will provide a test
skill at controlling a winter environment
mewhere between outdoor reality and
e centrally heated indoors. Treviso obvi-
sly has a milder climate than most
rtheastern winters. The only reliable-
seeming account of radicchio culture out-
side Italy that I have seen is in Joy Lark-
com's *The Salad Garden* (London: Wind-
ward). She is the only writer on the subject
who actually seems to have grown the
plant, and she recommends high polyeth-
ylene tunnels. But I would embark on this
only in an experimental spirit under
American conditions.

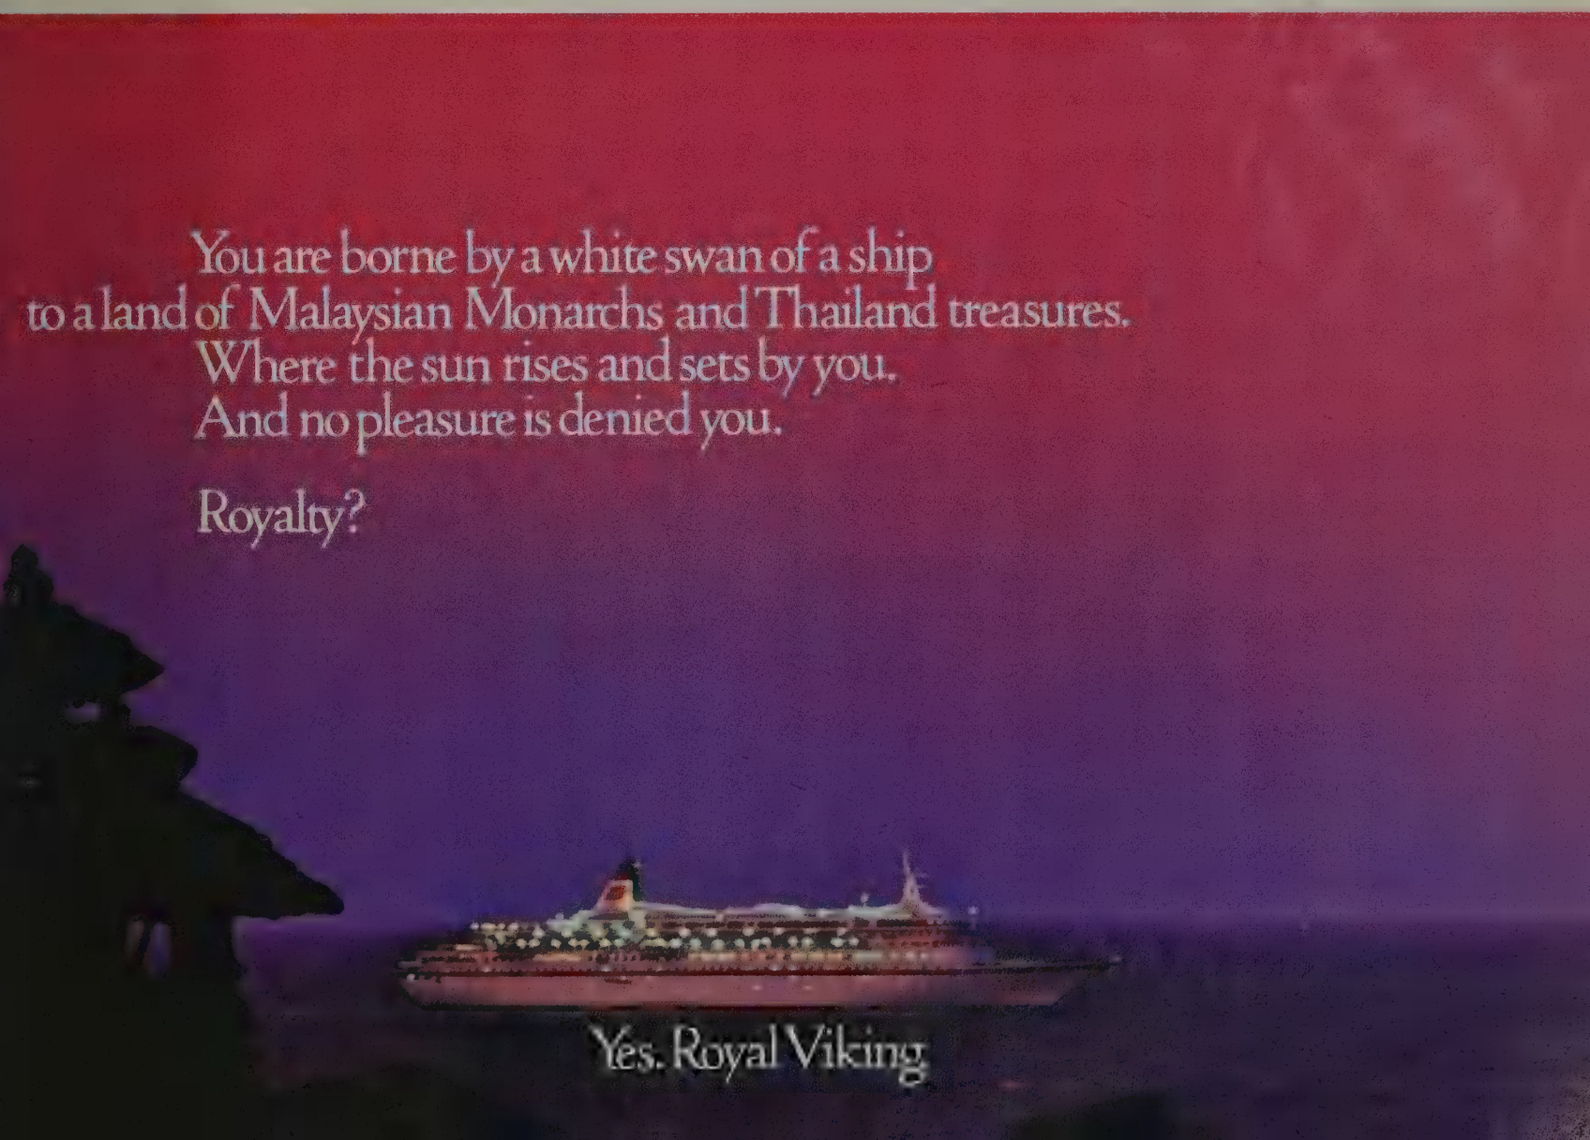
As a cook, however, I feel more confi-
dent about tackling radicchio. First of all,
there's no mistaking it. If you serve it raw,
it adapts well to new companions and goes
into salads of almost any mix. And if you
want to enact a sort of Linnaean pun, you
could serve it with the true endive we call
chicory. Or you could do what the Market
Dining Room in Manhattan's World
Trade Center does and mix it, shredded,
with its species mate, the true chicory we
call endive.

Radicchio can also be cooked. I first ex-
perienced radicchio grilled in olive oil one
New Year's Eve in the early eighties. This
winter, the same elegantly bitter mixture
of radicchio and olive oil flavors showed
up as a garnish for a concoction of salmon
mousse and crayfish at Dupuy Canal
House in High Falls, New York.

This was a relatively restrained use of
radicchio during the high tide of its fame
and glamour. The *Times* data search
turned up dozens of references to radic-
chio extravaganzas in restaurant reviews.
Times critics were not given pause by
such edible gewgaws as a "duck salad con-
sisting of leaf lettuce and radicchio leaves
tossed with slivers of duck in a raspberry-
accented vinaigrette" or the west coast
Mexican *nouvelle cuisine* menu that in-
cluded radicchio and smoked chicken ta-
cos with red chili mayonnaise.

In their hysterical lunging after novelty,
American chefs have overlooked some
very fine, traditional Italian radicchio
dishes. I had never had pasta or risotto
with cooked radicchio until I traveled to
Rome last year. On returning home, I was
fortunate enough to discover recipes for
these splendid dishes (see below) in a
cookbook I had somehow previously over-
looked: *Pasta and Rice, Italian Style*, by
Efrem Funghi Calingaert and Jacquelyn
Days Serwer. The first lady is an Italian
cooking teacher; the other an American
with experience working in Italian restau-
rants. Their recipes reflect what one actu-
ally finds today in Italian restaurants, in-
cluding radicchio in its proper cultural
context.

*Raymond Sokolov is a writer whose spe-
cial interest is the history and preparation
of food.*



You are borne by a white swan of a ship
to a land of Malaysian Monarchs and Thailand treasures.
Where the sun rises and sets by you.
And no pleasure is denied you.
Royalty?
Yes. Royal Viking

Roan Mountain, North Carolina

by Robert H. Mohlenbrock

An early name for the area was Cloudland. From a broad base 2,500 feet above sea level, Roan Mountain rises to 6,285 feet, forming a rounded divide that extends nearly five miles along the North Carolina–Tennessee line. On either side of the divide, rounded spurs alternate with V-shaped valleys. Oak and chestnut forests once covered the lower slopes, but these were cleared many years ago for cultivation and timber (a blight that struck the chestnuts in the late nineteenth century helped to speed the process along). Above 3,500 feet, however, large tracts of natural habitat persist, including catawba rhododendron gardens that offer a spectacular show in June. The rhododendron communities and other treeless areas, referred to as balds, seem inexplicable freaks in an otherwise forested area.

In a band about 3,500 to 5,000 feet above sea level, where the deep, rich soil is relatively free of surface rocks and outcrops, American beeches and sugar maples may stand seventy feet tall. Yellow birch, apparently because it is better adapted to cooler temperatures, becomes common near the upper limits of this forest community, which also has a scattering of shorter trees—sweet birch, Ohio buckeye, mountain and striped maples, and smooth serviceberry. There is a shrub layer composed of hobblebush vibernum, alternate-leaf dogwood, and elderberries; beneath it, a number of wildflowers span the growing season. Jack-in-the-pulpit blooms in early spring, followed by the great star chickweed, with its large, white flowers. Orange jewelweed blooms in summer, and the branched white aster in the autumn.

Upslope, the beeches and sugar maples become smaller and are more widely spaced as they reach their environmental tolerance limits. Above 5,400 feet and all the way to the summit—where the climate is cooler, snow more plentiful in winter, and the winds stronger—they are replaced by a coniferous forest of red spruce and Fraser fir. Scattered among the cone-bearing evergreens, which raise their needle-clothed branches to nearly ninety feet, are such deciduous trees as yellow birch, striped maple, mountain ash, and sweet buckeye. Beneath the canopy trees there is a modest shrub layer, which includes an occasional rhododendron. Aided by thick summer fogs, which hover over the mountain, mosses and lichens cover more than half the ground surface, often edging their way up the tree trunks for four or five feet, and wispy strands of *Usnea* lichens hang from the tree limbs. A few flowering herbs, such as mountain sorrel, foamflower, and purple turtlehead, rupture the moss cover.

The spruce-fir forest occupies Roan Mountain's most rugged terrain, where numerous exposed rock outcrops occur. This stony topography is particularly evident at Roan High Bluff, a scenic overlook reached by trail from the rhododendron gardens at Roan High Knob. Trees toppled by wind or scarred severely by lightning testify to the harsh climate.

But the plant communities known as balds evoke the most interest on Roan Mountain. Some area residents still refer to them as slicks because of their shiny appearance from a distance. A.F. Marks, who has studied the southern Appalachian balds thoroughly, defines a bald as "an area of naturally occurring treeless vegetation located on a well-drained site *below* the climatic treeline in a predominantly forested region."

Three kinds of balds occupy the upper slopes of Roan Mountain, all in the zone normally inhabited by the spruce-fir forest. Grass balds are the most common, generally occurring between 5,500 and 5,700 feet. Because they are devoid of most shrubs, they are sometimes called mountain meadows. Mountain oat grass forms a cover through which sheep sorrel, tickle-grass, and wild strawberry occasionally protrude. Some small mounds, called moss hummocks, support the growth only of mosses. At roughly the same altitude are also found the rarest of the Roan Mountain balds, the alder balds, which seem to have developed where there is more available soil moisture. These thick, shrubby stands of three- and four-foot-tall green alders are known from no other area in the Carolinas.

The showplaces of Roan Mountain, however, are the rhododendron balds, located mostly on the southeastern side of the divide at between 6,000 and 6,150 feet. At their peak in mid-June, these balds contain hundreds of brilliant rose-pink catawba rhododendrons, interrupted occasionally by patches of grassland. Here and there, a stray red spruce or mountain ash has established a foothold and overtops the rhododendrons, but few plants grow beneath the shrubs because their densely crowded, thick leaves let little light reach the ground. The rhododendrons also produce a network of feeder roots in the upper two inches of the soil, excluding most herbaceous plants. The Pisgah National Forest has provided parking areas near Roan High Knob, where trails permit visitors to wander through 600 acres of rhododendrons.

Biologists have proposed many theories to explain the origin of the balds. The first

photographs by Jim Bones

Above, a skeleton of a rhododendron grove is one of the treeless areas atop Roan High Knob; opposite, catawba rhododendrons blossom on Roan Mountain.

suggestion, made near the turn of the century, was that balds were areas where the trees had been damaged and ultimately killed by winter ice storms. Although ice does damage some of the trees on Roan Mountain, large acreages of trees would probably not be wiped out while the surrounding forest remained intact. Years ago a prominent Nebraska botanist suggested instead that fire was the primary cause for the development of the balds. In the southern Appalachians, however, fires are normally followed by the invasion of fire cherries, which do not seem to have been an important part of the Roan Mountain flora. The treeless glades and hill prairies of the Midwest are accounted for, at least in part, by their western exposures, which leave them with soil so dry that trees cannot grow. Although many of the balds on Roan Mountain are on southwestern slopes that receive drying winds, their soil is not significantly drier than in the adjacent forests, and trees can grow there if given a chance. Still another suggestion is that Indians cleared the region of trees and maintained the treeless areas for campgrounds and grazing by animals, but there is little evidence of this.

The most plausible explanation for the origin of balds involves past climatic conditions and the reaction of vegetation to them. Typically, the upper elevations of the southern Appalachians support a coniferous spruce-fir forest. Below 5,000 feet, deciduous beech-maple forest prevails. About 4,000 years ago, a lengthy hot and dry period affected the region. The spruces and firs growing near their lower limits of tolerance gradually succumbed to the hot, arid climate and were replaced by beeches and maples. Subsequently, a cooling trend, which has continued to the present, made life difficult for the beeches and maples that had occupied this upper range. Many trees perished during the cold winters, and others fell because of severe winds, ice damage, and possibly even lightning fires.

The spruce-fir forest generally failed to reestablish itself in this zone because any seedlings that germinated soon perished in the absence of a protective tree canopy. The treeless zone was invaded instead by grasses, and the grass balds came into existence. The uppermost balds nearest the spruce-fir forest were eventually populated by rhododendrons, whose seeds came from the rhododendrons in the forest understory. Fir and particularly spruce seeds also fell into these adjacent balds, but the conditions necessary for their germination and survival apparently did not prevail. Those balds that have remained grass balds probably harbor very few rhododendrons because there is not a large rhododendron seed source near by.

Today, the balds of Roan Mountain are unstable communities. Some are expanding; others are shrinking. Where there is expansion, it is because mature trees that grow at the edge of the balds are exposed to more severe environmental conditions than those within the forest. In historical times, also, local settlers who used the balds as grazing areas for their domestic animals cut the bordering trees to provide more space. On the other hand, the edges of the balds are constantly threatened by the invasion of woody plants. The spruces and firs are potent seed sources. A seed may be blown beneath a clump of rhododendrons, whose shade permits the conifer seedling to develop. On occasion, this seedling will grow and break through the shrub canopy, ultimately shading out the rhododendrons and killing them. There is thus a continuous ecological war between the balds and the adjacent forests.

"This Land" highlights the biological phenomena that can be explored in the 153 U.S. national forests. Robert H. Mohlenbrock is professor of botany at Southern Illinois University at Carbondale.

The Maya Enter History

Ancient hieroglyphs reveal the life stories and power politics of a ruling elite

by T. Patrick Culbert

The Maya civilization of southern Mexico and Central America has always enchanted both archeologists and the public. The image of giant temple pyramids looming out of the forbidding rain forest and the attraction of an undeciphered script holding unimaginable secrets have helped surround the Maya with an aura of romance. But in recent years, archeological research has stripped away many of the layers of mystery. Most important, as a result of breakthroughs in the interpretation of their hieroglyphic writing, the Maya of the Classic period (A.D. 250–900) have entered history. The names of Maya rulers can now stand beside those of the Pharaohs of Egypt and the legendary kings of Mesopotamia.

The Maya are relative newcomers to the accepted roster of great civilizations of antiquity, for not until the 1840s were their spectacular architectural remains brought to the attention of the public in America and Europe. At that time, New York lawyer and travel writer John Lloyd Stephens, accompanied by the English artist Frederick Catherwood, made two trips into the Maya area to explore some of the most important ruins. His travel books became best sellers in six languages and, for the first time, the educated layperson heard such magic names as Palenque, Copán, and Chichén Itzá.

Stephens was a careful observer who avoided the flights of fancy—the Maya as strayed Phoenicians or lost tribes of Israel, for example—that plagued the accounts of many who followed him into the rain forest. When he sought meaning in the things he encountered, Stephens proceeded cautiously, guided by the evidence and by his knowledge of ancient civilizations in other parts of the world. He reached the logical conclusion that Maya sculptures of individuals were the portraits of "kings, chieftains, or sages" and remarked that some of the hieroglyphs "reminded us strongly of the Egyptian method of giving the names of the kings and heroes in whose honour monuments were erected." Musing upon the site of Copán, he noted, "We considered that in its medallion tablets the people who reared it had published a record of themselves, through which we might one day hold conference with a perished race, and unveil the mystery that hung over the city."

A major exhibition, "Maya—Treasures of an Ancient Civilization," will begin its tour at the American Museum of Natural History, April 26 through July 28. Organized by the Albuquerque Museum of Art, History, and Science, the exhibition features objects on loan from the governments of Mexico, Guatemala, and Belize as well as from United States and Canadian museums. The selection of 275 artifacts, which were recovered from Maya tombs and sites, includes massive carved stone stelae, jade and shell jewelry, golden figurines, and painted ceramics. For the exhibition's complete itinerary, see page 116.

Stephens's hopes were to be long disappointed, however, for research in the century following his explorations turned to such archeological basics as chronology and site description, while the writing system proved intractable to interpreters. Nevertheless, a great deal of information was gained. The Maya calendar, the one readily decipherable part of the inscriptions, showed that dated monuments had been erected between about A.D. 250 and 900—a period promptly dubbed the Classic. This had been followed in the northern half of the lowlands by a vigorous post-Classic period, during which such famous sites as Uxmal and Chichén Itzá saw their major periods of occupation. Excavation at principal sites also revealed levels beneath the Classic remains, showing that centuries of development had preceded the appearance of Classic traits. By the 1940s, archeologists could identify chronological sequences for both ceramic and architectural styles.

Sylvanus G. Morley, dean of Mayanists at the time, listed 116 major sites in a summary of Maya archeology published in 1948. A typical site contained several groups of stone structures, separated from one another by some distance and often connected by impressive paved causeways. Structures were classified as either temples or palaces. Temples were placed atop giant pyramids, which were often taller than modern ten-story buildings. Temple buildings had little usable space, just one to three narrow rooms, arranged one behind the other. Access was through an exterior doorway at the top of a steep stairway, which led up the face of the pyramid. Similar structures were being used for religious ceremonies when the Spaniards first arrived in Mexico in the 1520s.

Palaces were quite different; resting on low platforms rather than pyramids, they were sometimes two or three stories high and had many rooms and entrances. Some archeologists believed these structures were residences for an elite, as implied by the designation *palace*; others thought that they might have been administrative buildings, storehouses, or quarters for priests or students.

Charles Henneghien; Bruce Coleman

The ancient Maya lived in both highland and lowland areas, from what is now southern Mexico through Guatemala, Belize, El Salvador, and Honduras. (Teotihuacan, located near modern-day Mexico City, was a populous non-Maya center whose political influence has been detected at Maya sites.) Classic Maya culture flowered in the lowlands from A.D. 250 to 900. In the ninth century, the civilization collapsed in the central and southern lowlands, and such sites as Tikal, Copán, and Palenque were depopulated. But in the lowlands farther north, as well as in the highlands to the south, Maya groups continued to thrive until the arrival of the Spaniards in the 1520s.

Joe LeMonnier

Because there were no houses between these groups of stone buildings, the impression arose that ancient Maya sites had been vacant ceremonial centers, whose permanent inhabitants consisted of only a small group of elite persons, priests, and craft specialists. Archeologists reasoned that, like modern Maya villages in the neighboring highlands of Guatemala, these centers filled with people only during times of ceremonies, when the lower classes thronged in from the countryside.

Maya art provided more puzzles than answers. Sites were full of stone carvings—upright slabs, or stelae; door lintels; occasional wall panels—that showed elaborately dressed individuals, usually in formal poses. The carvings seemed to be full of religious symbols and sometimes included fantastic, obviously mythological animals, such as the two-headed serpent that writhes through the sky in some compositions. Were the individuals portrayed the kings, chieftains, and sages that Stephens had imagined, or were they instead priests dressed for ceremonies—or perhaps the gods themselves?

The carvings were accompanied by inscriptions, but these resisted decipherment. The Maya calendar had been interpreted by about 1900, and substantial progress had been made in unraveling a complicated series of countings and calculations having to do with calendrical and astronomical events subsidiary to the dates themselves. So it was possible to date carvings and sites with great accuracy, but impossible to say what had gone on at the dates so proudly proclaimed. Since many of the inscriptions dated to the end of Maya calendric periods, especially the end of *katuns* (which were periods of approximately twenty years), the opinion grew that perhaps the Maya had been celebrating the passage of time itself, without reference to historical events.

Despite an accumulation of archeological information, the Maya as people were as remote as ever. As imagined, the elite, nearly alone in their vacant centers, had few concerns about the everyday world and were free to devote themselves to esoteric spiritual matters. They obviously devoted a great deal of energy to erecting mighty temples and presumably using them for ceremonies to honor their gods. They investigated astronomy, mathematics, and calendrics with vigor and an almost compulsive precision. They prayed and philosophized and perhaps celebrated the passage of time, but whether they schemed and struggled for power and material possessions like mortals in most cultures was not clear from the archeological record. Or perhaps such matters were not clear to archeologists, who seemed bent on stressing how the Maya differed from the rest of humankind.

After World War II, the profession of archeology entered a period in which traditional theories and methods were vigorously challenged. New questions were asked and new kinds of data were gathered to answer them. The upshot was that a strong interest in people was added to the customary concern with things. Maya archeology was no exception to this trend. Mayanists, once interested primarily in large stone structures, began to search for the houses of the ordinary Maya.

What they discovered were "house mounds," low dirt platforms surrounded by stone retaining walls. On these the lower classes had constructed houses of poles, with thatched roofs. These building

Left: Temples line the front edge of Tikal's North Acropolis, a huge platform upon which eleven temples stood. The two shown here, stripped of later stages of construction, were built over the tombs of two Early Classic rulers, Curl Nose and Stormy Sky. Below: Chitam, the last identified ruler of Tikal, was honored by this stela (carved tablet) and altar erected in A.D. 77.

Peter Menzel

aterials perished in the steamy jungle nvironment, but postholes had been left the plastered floors, and occasional im-ressions left in mud that had hardened hen houses burned. Maya sites had not een vacant ceremonial centers at all. The eemingly empty spaces between stone uilding groups were crammed with ouse mounds, indicating that tens of housands of inhabitants had lived within alking distance of the centers of the larg-st sites.

This discovery explained where the la-or to build temples and palaces had come om. It also made it less likely that the lite had devoted themselves to philosoph-al speculation, for large communities de-hand organization and administration. dditional data that cried for more orldly interpretations of Maya society ame from major excavations such as the Tikal Project, run by the University of Pennsylvania between 1956 and 1970. Tikal was huge, its population exceeded 30,000, and the indications of kingly splendor were inescapable.

Two tombs and a stela found near the Great Plaza of Tikal were to prove of particular significance in the light of evidence later provided by inscriptions. The tombs, located at the north edge of the Great Plaza, were covered by a succession of major temples. The principal individual in the earlier tomb was accompanied by the skeletons of nine other people, which archeologists interpreted to be sacrifices at the time of death or at the burial ceremonies. In the later tomb a Maya inscription on the wall indicated a date equivalent to March 18, 457. Both tombs included offerings fit for kings: quantities of jade and shell, the bodies of birds, and a profusion of ceramics, including several masterful effigy figures. But the most surprising feature was that both burials included many offerings whose symbolic decoration suggested a connection to Teotihuacan, a vast non-Maya site just outside modern Mexico City, more than 600 miles west of Tikal. Teotihuacan, which emerged as a major Mexican power in the second century, was the most influential site in Mesoamerica until the sixth century.

The puzzle deepened when a stela was discovered during the excavation of a temple that had been built over the site of the dated tomb. The stela, which must have originally stood in some outside location, was from the year 445, close to the date of the 457 tomb. Carved on its face was a typical Maya, garbed in all the finery of Early Classic costume. But this figure was flanked on the two sides of the stela by men who were certainly foreigners. Their faces lacked the characteristic Maya profile, and their costumes were those worn at Teotihuacan. In addition, they carried spear throwers, weapons used in Mexico but not by the Maya, and had shields that showed the face of Tlaloc, the chief god of the Mexicans.

To find Teotihuacan influence in Tikal was not in itself surprising. In the fourth and fifth centuries, Teotihuacan, with a population of more than 150,000, was one of the great cities of the world—a manufacturing and trade center whose products were carried throughout Mesoamerica. But archeologists did not expect to find this influence in the tombs of two of Tikal's most important men or—even more puzzling—on what was regarded as the most sacred Maya medium, a carved stela. What could be the meaning of the apparent encounter pictured on the stela? Pragmatic, commercial, probably militaristic, the representatives of Teotihuacan would not have been dazzled by the Maya's ability to record the passage of time in excruciating detail. If a Tikal lord met with men from Teotihuacan, they must have talked business and power politics.

During the period in which the Tikal Project was producing such marvels, Maya hieroglyphic writing—after decades without significant progress—began to yield to interpretation. The first breakthrough was relatively small, involving just a single class of glyphs, or symbols. In a paper published in 1958, the German epigrapher Heinrich Berlin demonstrated that Maya sites yielded "emblem" glyphs, which named or were otherwise associated with the sites themselves. By itself, Berlin's revelation did not threaten the assumption that the inscriptions dealt almost entirely with ritual and

calendrical calculations, for they might well have been referring to the sites as great ceremonial centers.

The next breakthrough, however, was devastating to the old ideas. In 1960, Tatiana Proskouriakoff, a leading researcher with the Carnegie Institution of Washington, published a paper outlining a pattern she had observed in the inscriptions at Piedras Negras. Proskouriakoff noticed that the stelae, each of which bore a date, had been erected in sets containing from two to eleven stelae. The earliest stela in each set showed a scene that Proskouriakoff dubbed the "ascension motif"—a picture of a man seated in a niche to which a ladder and footprints led. One particular glyph was always associated with this motif. Proskouriakoff deduced that the ascension motif and its associated glyph referred to the inauguration of a ruler, who was pictured taking his throne. She also identified which glyphs named the rulers involved. Later stelae in the set showed the same individual in other activities. Finally, at what was a reasonable length of time for a human life span, the set came to an end and was followed by a new set commemorating the ascension and career of another ruler.

Proskouriakoff's interpretation was so convincingly demonstrated that there was no longer any question that large sections of the Maya inscriptions were historical in character. One revelation followed another. In addition to emblem and name glyphs, glyphs for birth, death, and capture were identified. Rapidly, dynastic lists were developed for prominent sites, including records of outstanding events in the life of each major ruler. The most important sites had been ruled by a series of great families, such as the Sky family of Tikal and the Jaguars of Yaxchilán. These families had been intricately interconnected through marriages and alliances and had continually jockeyed for position in relation to one another and for control and influence at lesser sites.

One story of political maneuvering begins in the middle of the fourth century, when a man named Jaguar Paw ruled Tikal. At Jaguar Paw's death, his son was bypassed, and the throne went to Jaguar Paw's son-in-law, a man called Curl Nose. Curl Nose was not a member of the Tikal royal family; instead, he seems to have originated at Kaminaljuyu, a center in the highlands of Guatemala that was under strong influence from Teotihuacan. The earlier of the two Tikal burials described above, which were rich with symbols of Teotihuacan, belonged to Curl Nose.

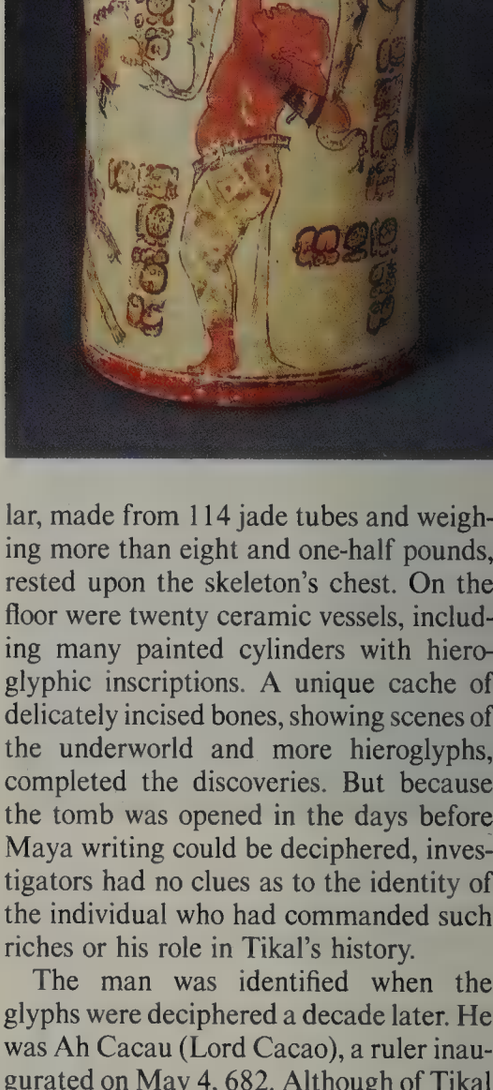
Teotihuacan may well have been powerful enough to influence royal succession in Tikal, first by having a favored leader marry into the ruling family and then by having him crowned king. The inscriptions give no hint of a power struggle, but one can easily imagine a pro-Teotihuacan faction in Tikal arguing vigorously for the benefits to be gained from alliance with the great commercial city. In any case, Tikal became rich and powerful during the reign of Curl Nose. He was succeeded by his son, Stormy Sky, who gained even greater glory as the power of Tikal spread throughout the lowland Maya area. Stormy Sky maintained strong relationships with Teotihuacan, for his was the second burial with Mexican mementos and he is the Maya—flanked by emissaries from Teotihuacan—pictured on the stela. Unfortunately, the parts of the stela's inscriptions that have been interpreted so far provide no details about what event took place at that meeting.

Stormy Sky died about 455, but his influence was to reemerge more than two centuries later. In 1959, Tikal Project archeologists decided to investigate Temple 1, a seventh-century edifice that closes the east end of the Great Plaza at Tikal. By tunneling into the base of the pyramid supporting the temple, they hoped to find a major tomb, for on other occasions tombs had been found on the central axes of temples. The search was a long one, but after more than two years and 400 feet of tunnels, the archeologists came upon the giant limestone slabs that capped the top of the tomb.

When the tomb was opened, their long, painful effort was amply rewarded. Inside lay the skeleton of an elderly male, surrounded by a remarkable store of offerings. Shells, pearls, and large quantities of jade greeted the excavators. A great collar, made from 114 jade tubes and weighing more than eight and one-half pounds, rested upon the skeleton's chest. On the floor were twenty ceramic vessels, including many painted cylinders with hieroglyphic inscriptions. A unique cache of delicately incised bones, showing scenes of the underworld and more hieroglyphs, completed the discoveries. But because the tomb was opened in the days before Maya writing could be deciphered, investigators had no clues as to the identity of the individual who had commanded such riches or his role in Tikal's history.

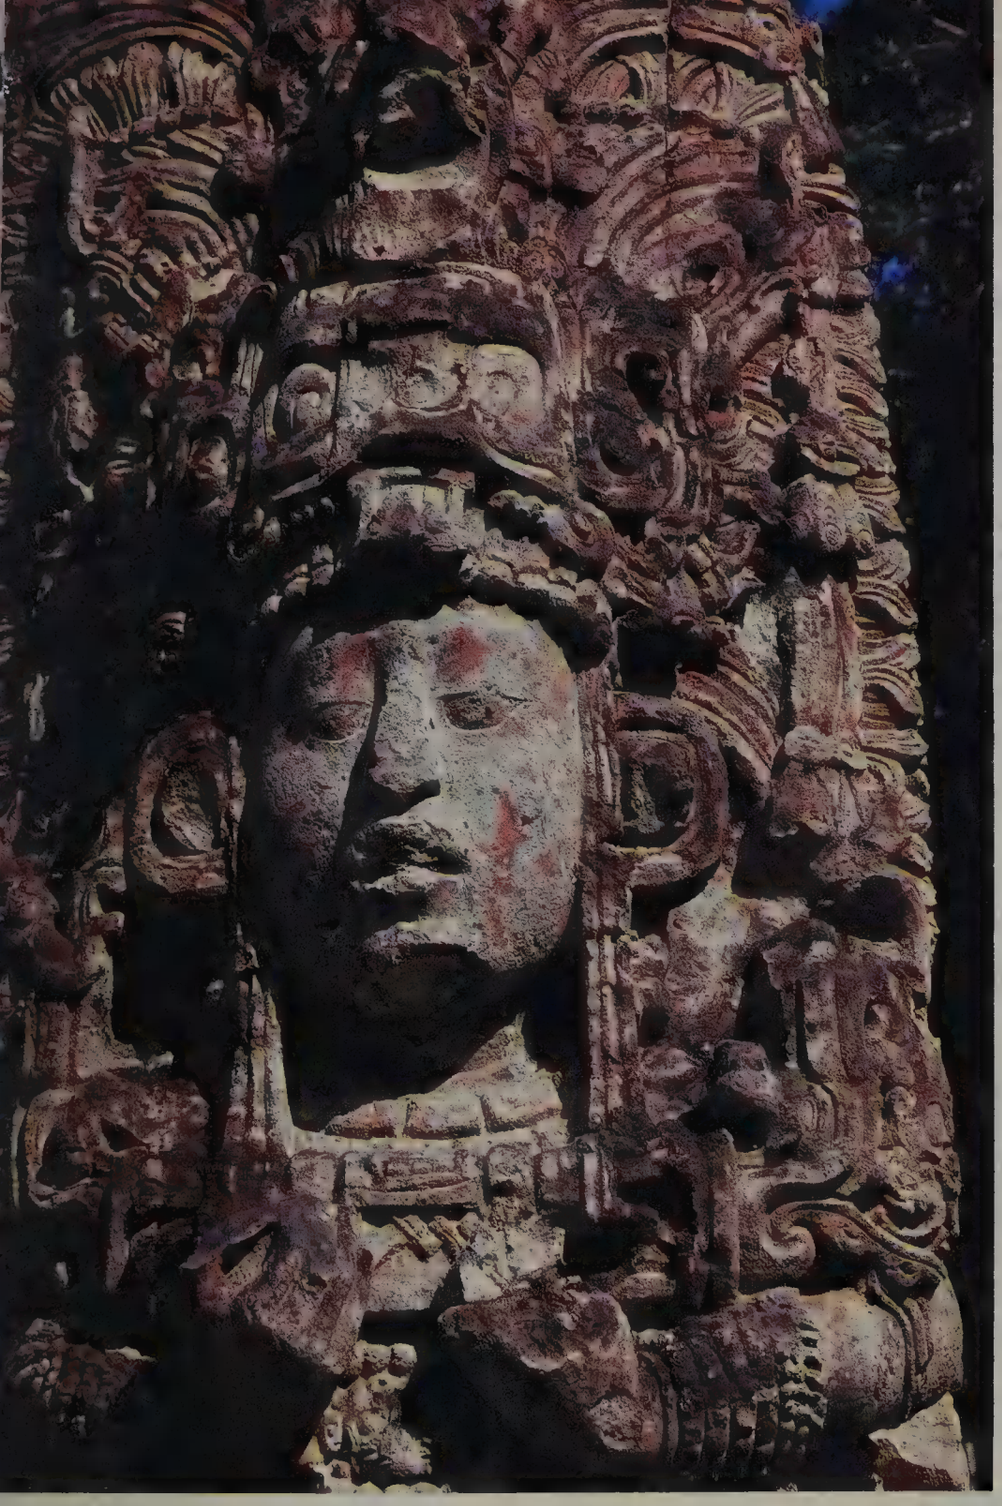
The Altar Vase, recovered from a burial at the site of Altar de Sacrificios, is thought to depict an actual burial ceremony that took place about A.D. 754. The hieroglyphic writing gives some historical information, but it does not identify the snake-handling participant.

Stuart Rome; Courtesy of the National Museum of Archaeology, Guatemala



The man was identified when the glyphs were deciphered a decade later. He was Ah Cacau (Lord Cacao), a ruler inaugurated on May 4, 682. Although of Tikal royal blood, Ah Cacau was not born and raised at Tikal. He seems to have been a member of a branch of the royal house that had left the site some time earlier, perhaps during a period of political turmoil. The most important feature of his ancestry was that Ah Cacau was—or at least asserted he was—a direct descendant of Stormy Sky, in whose legendary mantle he proudly wrapped himself.

Ah Cacau's predecessors are not well known, for there is a long gap in the Tikal inscriptions. One interpretation, however, is that Ah Cacau took the throne by force



B. Kielczynski; The Stock Market

A stela from Copán, in the deeply carved style characteristic of that site, shows a Maya noblewoman of A.D. *726. Women are rarely depicted in formal Maya art; this one may have been the wife of the Copán ruler.*

om someone he considered a usurper. Whatever the circumstances of his acquisition of power, Ah Cacau stressed the legitimacy of his rule and traded upon the reputation of his ancestor Stormy Sky. The Maya calendar offered him an unusual opportunity to do so, for thirteen *katuns* (about 260 years) had passed since Stormy Sky's inauguration. At that interval, the calendar reached the end of a cycle and began over again. Because the Maya believed that history was cyclical, they anticipated that events of the previous cycle would be repeated. In choosing the thirteen-*katun* anniversary of Stormy Sky's inauguration for his own inauguration, Ah Cacau implied that his reign would rival that of his fabled predecessor. Such proved to be the case, for he led the city into what was to be the period of its greatest glory. Major construction was undertaken during Ah Cacau's reign, and in the eighth century Tikal emerged from a period of relative political obscurity to become one of the most powerful Maya sites.

Maya art takes on new meaning now that scholars know it depicts historical characters rather than priestly ceremonies or gods. The carved stela is the most formal medium the Maya used to glorify their elite. Most stelae portray the stiffly posed ruler bearing the elaborate costume and insignia of office. Additional scenes, accompanied by inscriptions, were carved on the lintels and wall panels found at certain sites. These scenes, involving several characters, portray ceremonies of investiture, battles, and subjects kneeling before their ruler.

Between 600 and 800, the Maya began making a type of multicolored painted pottery that sometimes showed historical and mythological characters in a variety of lively activities. These scenes, usually painted on cylindrical vessels found only in the richest of burials, include some of the great masterpieces of Maya art. Among the most famous is the Altar Vase, recovered from a woman's burial at the medium-sized site of Altar de Sacrificios. The vase depicts a burial ceremony. Two people are shown dancing, a man in jaguar-skin tights and a bald, pudgy individual holding aloft a giant snake. Four seated people watch the proceedings. The glyphs suggest that the ceremony was attended by representatives from several large sites. The dancing figure in jaguar costume is identified as Bird Jaguar, a ruler from Yaxchilán, while one of the seated individuals is from Tikal. Apparently the woman whose burial ceremony is pictured was related to the dynasties at both these sites, and both sent representatives to the funeral.

The participation of outside representatives at burial ceremonies is also evident at the tomb of Ah Cacau at Tikal. Among the offerings in the tomb was a set of nine painted cylinders, each portraying a king seated upon a throne. These are not portraits of Ah Cacau, for both the pictures and inscriptions indicate they are other lords. Furthermore the paintings are not the work of master artists. Instead, they range from a few pieces of acceptable quality to some of excruciatingly bad workmanship. A plausible explanation for why vessels that display such an abysmal lack of talent should have been placed in the tomb of one of the most important Maya leaders is that they were done personally by visiting rulers as a mark of respect for their departed colleague.

Archeological views of the Maya have changed drastically in a single generation. From a remote and mysterious people ruled by holy priest-kings devoted to lofty philosophical speculations, they have been transformed into a historical reality whose dynasties have names as familiar to specialists as those of the Ramses and Hapsburgs. In the process, Maya kings have gained humanity. They engaged in political intrigues, married for power and profit, and were as obsessed that future

generations should know of their greatness as were the kings of other civilizations.

These new insights, combined with archeological data on site size, structure, and location, have given us a much better understanding of Maya civilization at its height. In the Late Classic—the period from which most of the inscriptions date—the lowland Maya area apparently was divided between some half dozen regional states. Major sites such as Tikal, Palenque, and Copán served as capitals, with secondary sites bound to them through conquest, alliance, and elite intermarriage. The political structure may have been feudal, with paramount rulers at the capitals struggling to maintain the loyalty of unruly hordes of lesser nobles.

We do not know why Maya civilization disappeared from the central and southern lowland region in the ninth century. Inscriptions ceased, new construction halted, and a massive decline in population left huge areas almost unpopulated. In light of the climax reached by the Classic Maya, this collapse seems even more profound.

Both the success and the failure of the Classic Maya must have had roots in the activities of the humble people revealed by archeological research. The number of house mounds dating to the Late Classic leaves no doubt that the population had become extremely large—far too large to have been supported by the simple slash-and-burn agriculture generally regarded as the soundest approach to farming in the rain forest environment. Archeological remains indicate that extensive systems of terraces were constructed in parts of the lowlands and that large tracts of low-lying seasonal swampland were converted into farmland by digging drainage canals. This high level of population and production may well have overtaxed the fragile rain forest environment. But the activities of the Maya rulers are also at issue, for problems of management and control must have become acute as the population grew. The failure of the elite to develop techniques for the successful management of a rapidly expanding system may have been an equally critical factor in the Maya collapse. □

The Adivino, the House of the Magician, is a typical temple, a small building atop a pyramid. It was built about A.D. 800–1000 at Uxmal, a center in the northern lowland zone.

A New Museum Program

INTRODUCING
MEMBERS' NEW YORK WEEKEND

A special New York tour program designed exclusively for our Members. It's a convenient and economical way to enjoy all the wonders that New York and the American Museum of Natural History have to offer.

THE TOUR PROGRAM INCLUDES:

Two nights in one of New York's finest hotels. Stay at the Waldorf-Astoria, The Plaza or Parker Meridian. Minutes away from New York's famed theater, shopping and eating districts and only a short ride away from the Museum itself.

Two complimentary meals: Enjoy a full breakfast at your hotel and a spectacular brunch at the new American Museum Restaurant, a charming greenhouse-like dining room nestled in one of the Museum's interior courtyards.

The Official Museum Guide and a Highlights Tour: As soon as you make your reservations we will send you the Museum's Official Guide book to introduce you to our fabulous treasures. And then when you come to the Museum, take a Highlights Tour which provides fascinating insights into the Museum's most popular halls. You'll see the Star of India sapphire, Tyrannosaurus Rex, the enormous Blue Whale, a ceremonial canoe of the Haida Indians and much more. After the tour relax in our private Members' Lounge or take advantage of your Members' discount at one of our gift shops.

Free Planetarium and NatureMax Tickets: Journey through the heavens in the Planetarium's famed sky theater and enjoy the cinematic experience of a lifetime at NatureMax, with a movie screen four stories high and over sixty feet wide. (One of only 20 such facilities in the Western Hemisphere!)

Personalized Service: Our travel service representatives at Planetarium Travels Inc. will help you customize your New York Weekend to suit your needs and tastes. They will be glad to arrange for theater or concert tickets, reservations at New York's top restaurants, a carriage ride through Central Park or a special city tour. They can also arrange for special discount air fares to New York on American Airlines, the official airline of the Members' New York Weekend.

Special Exhibitions: The Museum presents an exciting schedule of special exhibitions throughout the year. For example, opening this April: *Maya: Treasures of an Ancient Civilization,* the first comprehensive exhibition of the art treasures of the Maya, and *John James Audubon: Science into Art,* commemorating the 200th anniversary of his birth.

TOUR PROGRAM PRICE: $92.50 per person, per night, tax included (based on two nights double occupancy, includes accommodations at deluxe hotel, two meals, Planetarium and NatureMax Tickets, Museum Highlights Tour and the Museum's Official Guide book). Rates also available for families and individuals.

Call or write today for reservations, brochures and more information.

(In N.Y. State call 212 595-1567)

WRITE TO: Members' New York Weekend
108 West 81 Street
New York, New York 10024

The New York Weekend Program is available throughout the year but it is subject to space limitations. So book your reservation now.

State of the Earth

Nearly five billion, and growing, we are straining earth's environment to an unprecedented degree. As human pressures build, the relationships between people and their natural support systems reach key

Illustrations by Alan E. Cobe

thresholds, leading to breakdowns. The broad strokes of this mid–decade report often show a frightening drift in a gloomy direction. Yet some fine strokes show bright examples of moves toward a healthy, sustained balance between humans and their natural resources. Our decisions and actions (or inactions) in the remaining years of this decade will affect the fate of all life on earth in the next decade . . . and century. In concert, we will determine whether we are breaking down or breaking out.

Nowhere is the breakdown of natural systems more tragically evident than in Africa, where famine is spreading rapidly. In 1970, Africa was essentially self-sufficient in food; by 1984, however, some 140 million Africans—out of 531 million—were fed with grain from abroad. The decline in per capita food production has been attributed to drought, but the causes are more fundamental: the fastest population growth in history, widespread soil erosion, and the neglect of agriculture by African governments.

The deterioration of environmental systems can be seen in industrial and developing countries alike. Acid rain and air pollutants may be destroying the forests of central Europe even faster than the ax and the plow destroyed those of India and El Salvador. Little attention has been paid to the economy–ecosystem relationship, and our understanding of stresses on ecosystems is far from complete.

National energy policies could determine the extent and pace of a worldwide change in climate. Population policies may determine whether Africa becomes a wasteland. The scale of environmental disruptions we face lends urgency to our efforts to return to a sustainable path—to bring population growth and our economic and social systems into a long-term balance with the resource base that supports us.

Lester R. Brown

Erosion of productive soils by wind and water is changing the face of

the earth, from subsistence fields in Ethiopia's highlands to thousand-acre swaths of corn and soybeans in the Mississippi valley. One of the first scientists to assess the dimensions of world soil erosion was geologist Sheldon Judson, who estimated that the amount of river-borne soil sediment carried into the oceans had increased from 9 billion tons per year before the introduction of agriculture and grazing to 24 billion tons per year in the late twentieth century. Humans have accelerated the flow of soil to the seas.

Soil erosion is steadily speeding up and now afflicts both industrial and developing countries. Only the ninefold increase in fertilizer use and the near tripling of the world's irrigated cropland since mid-century have masked the effects of soil erosion on crop yields and harvests. Yet as of 1984, the worldwide loss of topsoil from cropland in excess of new soil formation totaled some 25 billion tons.

Topsoil is the key to productive agriculture. Rich in organic matter, it shares more characteristics with the plant life it supports above than with the mineral layers beneath. It is the medium in which roots grow, soil animals flourish, and water is stored. Although in a few regions fertile soils are yards deep, over most of the world's surface the mantle of topsoil on which agriculture depends is only six to eight inches thick. The loss of this thin layer may soon compromise economic progress and political stability.

While detailed information on soil erosion from farmers' fields is available for only a few countries, data on the sediment load of the world's major rivers and on the movement of wind-borne soil over the oceans do provide a broad-brush view of soil erosion at the continental level. Chinese scientists report that the Huang He (Yellow River) carries 1.6 billion tons of soil to the ocean each year. India's Ganga River deposits 1.5 billion tons into the Bay of Bengal. The Mississippi, the largest U.S. river, carries 300 million tons of soil into the Gulf of Mexico each year. Although less than Asia's rivers, this load is soil from the agricultural heartland and is thus a major concern of U.S. agronomists.

Scientists have recently documented that vast amounts of wind-borne soil are also being deposited in the oceans. Island-based air sampling stations in the Atlantic, along with satellite photographs, indicate clearly that plumes of soil dust are being carried out of north Africa over the Atlantic. African soil spatters cars in Miami. Researchers link the unusually high levels recorded in 1983 to Africa's severe drought. Air samples taken at Mauna Loa, Hawaii, indicate a comparable transport of soil across the Pacific from the Asian mainland. The annual peaks in the samples (in March, April, and May) coincide with periods of strong winds, low rainfall, and plowing in the semiarid regions of north Asia. Scientists at Mauna Loa can now tell when spring plowing starts in north China.

The steady growth in demand for agricultural products contributes to soil erosion in many ways. Throughout the Third World, farmers are pushed onto steeply sloping, erosive land that is rapidly losing its topsoil. In the American Midwest, many farmers have abandoned ecologically stable, long-term crop rotations in favor of the continuous row

Kenya: Trees and Terraces to the Rescue

Kenya may be the only Third World country to launch a successful national program to conserve its soils. A decade old, the program shows not only that conservation is compatible with small-scale farming and a large rural population but also that such improvements can boost farmers' incomes.

Kenya identified soil erosion as its most serious environmental problem when preparing for a United Nations conference in 1972. With technical and financial aid from Sweden, the Kenyan Ministry of Agriculture launched several local projects in 1974. The program encouraged farmers to plant fruit, fuel, and fodder trees and to construct simple terraces on their fields to reduce the runoff of water.

By 1983, more than 100,000 farms had enrolled in the program, and 30,000 to 35,000 more farms were being added each year. Miles of newly constructed terraces to catch moisture and cutoff drains to divert erosive flows covered a distance equal to that between Sweden and the Cape of Good Hope. This success was achieved by involving farmers in the design of the program from the outset, providing them with seedlings of valuable trees, and establishing that crop yields could be increased in the short run. Higher yields reflected not only the saving of soil but also the retention of water and nutrients behind terraces.

The Kenyan experience demonstrates that a Third World country with limited financial resources can design and carry out an effective national soil and water conservation program with a minimum of outside aid. The significance of this achievement goes far beyond Kenya, for it means that other developing countries can mount an effective response to this serious agricultural problem.—*E.C.W.*

cropping of corn and soybeans, which leaves soils exposed to wind and water. In other areas, farming has extended into semiarid regions where land is vulnerable to wind erosion when plowed.

The loss of topsoil has two effects on farmers' ability to grow food: It robs the land of nutrients, and it degrades physical properties of the soil, such as its ability to absorb water. Erosion also increases the costs of food production. When farmers lose topsoil, they may increase land productivity by substituting energy in the form of fertilizer or through irrigation to offset the soil's declining water-absorptive capacity. Farmers losing topsoil may experience either a decline in their land's productivity or a rise in their costs. And when this happens, farmers can be forced to abandon their land.

The effects of erosion on harvests are not easily measured since they are usually gradual and cumulative. A survey of independent studies of soil erosion in the U.S. Corn Belt found that the loss of an inch of topsoil reduced corn yields by three to six bushels per acre. The average of these yield reductions was 6 percent. Results for wheat showed a similar relationship: Up to two and one-half bushels of wheat were lost on each eroding acre, yielding an average decline of 6 percent. At current rates, an inch of topsoil is lost from Iowa's cornfields and Montana's wheat fields every fourteen years. What are the long-term implications of erosion? One study, designed to predict the consequences of soil depletion in southern Iowa, showed that steady, uncontrolled soil loss would severely reduce yields of corn, oats, and soybeans, sacrificing as much as a third of the potential productivity of these crops.

Some governments have failed to support soil conservation enthusiastically because they do not see the link between topsoil losses and land productivity. Fortunately, new analytic tools are becoming available to scientists and policy makers. A method for calculating the ratio between actual and potential crop yields at various levels of soil loss has been developed for soils in the United States and is being tested on tropical soils in Hawaii, India, Mexico, and Nigeria. Its usefulness in estimating the global impact of erosion awaits a painstaking inventory of the world's soils.

The National Resources Inventory in the United States, conducted first in 1977 and then in 1982, is the most comprehensive national soil survey ever undertaken. Preliminary results for 1982 show that 44 percent of U.S. cropland is losing topsoil in excess of its tolerance level, a level roughly equal to the slow rate of soil formation. More than 90 percent of the soil eroding at excessive rates is on less than one-quarter of the cropland. These results attest to the need for action and point out where conservation efforts can most profitably be focused.

Two other major food-producing countries, China and India, have estimated their excessive soil loss. A study prepared for the Chinese government reports that five billion tons of soil and sand are washed into rivers each year. The government of India estimated in 1976 that soil degradation affected 370 million acres. Indian soil scientists concluded that the nation's croplands were losing a total of six billion tons of soil each year.

Despite considerable evidence of excessive soil erosion in the Soviet Union, the world's fourth major food producer, no comprehensive national survey has been undertaken. The best indirect evidence of pressures on Soviet soils is the 1984 decision to fallow more than 52 million acres of cropland, the highest level since the sixties. Despite expected grain imports of more than 50 million tons—the most by any country in history—the Soviets have decided to pull land out of production.

Although the changes in agricultural practices needed to check excessive soil erosion can be implemented only by farmers themselves, bringing erosion under control requires government involvement. Many farmers cannot easily determine whether their erosion is excessive. Measuring the

Just a word about the price of The Glenlivet. Preposterous.

Is the premium we place on The Glenlivet really so outlandish? No more so than the premium placed on great vintage wines and fine champagne cognacs. The reason? Taste. Just one sip and you'll know that The Glenlivet has a taste that's without equal.

The Glenlivet is Scotland's first and finest single malt Scotch, from Scotland's oldest licensed distillery. And, just as it always has been, this 100% Highland malt whisky is distilled from natural spring water and fine malt barley, then aged in oaken casks.

Only The Glenlivet's time-honored methods can achieve this unequaled taste. A taste that sets us apart. Its smoothness, body and bouquet are qualities found only in this unique Scotch.

Of course, some people may still insist that The Glenlivet is too expensive. We have just one word to say about that. Preposterous!

The Glenlivet

12-year-old unblended Scotch.

ALL IT TAKES IS SUCCESS.

The ultimate recognition from your banker. A gold MasterCard card.

gradual loss of soil requires scientific techniques and equipment; determining whether it is excessive requires information on tolerance levels for the particular cropland in question. Too, individual farmers may be unable to afford the necessary conservation practices. It may make sense for society to invest in soil conservation even if it is not profitable for the individual farmer. Only governments can calculate the long-term costs of soil erosion for a nation as a whole, including off-farm costs such as the siltation of irrigation reservoirs, hydroelectric reservoirs, and navigable rivers.

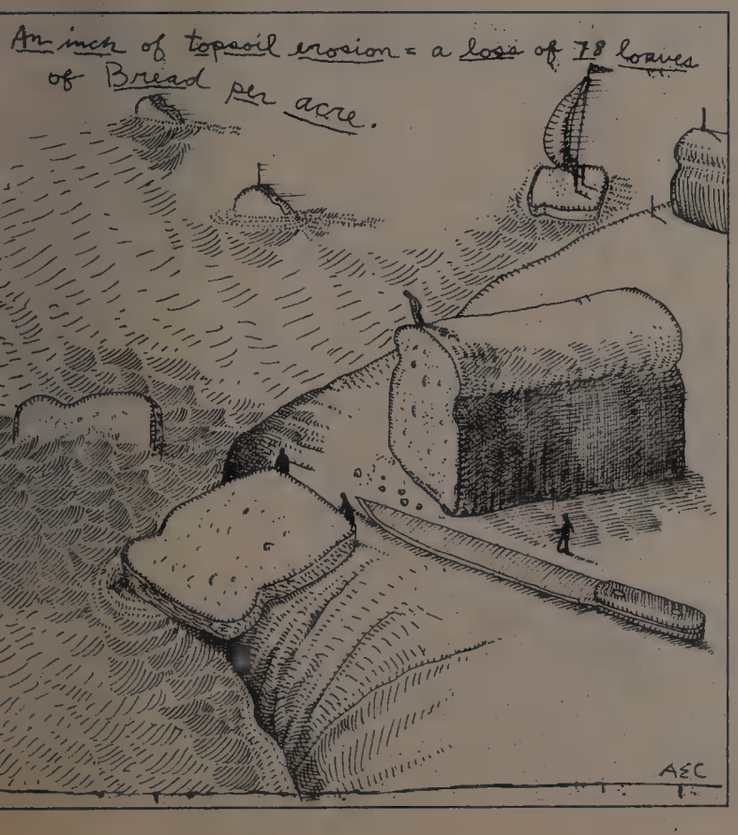
The United States unilaterally attempts to balance the world's supply and demand of agricultural commodities by withholding land from production during times of surplus. But little or no effort has been made to coordinate farm supply management programs that divert land with conservation programs designed to reduce soil erosion. Highly eroded cropland could be diverted to other uses, such as fuelwood production or grazing. This could bring the production of some grains down to a level that would reduce the need for government price supports and revive the profitability of farms.

In efforts to conserve soil, the world is faring poorly. There are few national successes, few models that other countries can emulate. The United States has the technology, the detailed information on its soil losses, and the resources to launch an exemplary soil conservation program, but it lacks committed leadership. Within the Third World, Kenya is one of the few countries to launch a successful national program to conserve its soils.

Over the past generation, many countries have, like Kenya, become unable to harvest enough to feed their people, but few have linked the shortages with the depletion of their soil by erosion. In many countries, people know that food prices are rising, but most do not know why. Understanding that lost soil means lower inherent productivity, which in turn means costlier food, is an important first step toward an international soil conservation ethic.

Uncontrolled soil erosion will eventually lead to higher food prices, hunger, and quite possibly, persistent pockets of famine. Although the world economy has weathered a severalfold increase in the price of oil over the past decade, it is not well equipped to cope with even modest rises in the price of food. The immediate effects of soil erosion are economic, but the ultimate effects are social.

Edward C. Wolf



Shocking glimpses of famished drought victims dramatize water's crucial

role in meeting basic human needs in Africa. And water shortages are persistently, if less dramatically, turning up throughout the world, posing far-reaching threats to our future food supplies and to economic progress.

By virtue of a cyclic flow between the sea, air, and land, fresh water is an abundant, renewable resource. Each year, the sun's energy lifts some 500,000 cubic kilometers of water from the earth's surface—86 percent from the oceans and 14 percent from land. (One cubic kilometer equals about 264 billion gallons.) An equal amount falls back to earth as rain, sleet, or snow, but fortunately a greater share falls over the land than is evaporated from it. The net effect of this solar-powered cycle is to distill and transfer 41,000 cubic kilometers of water from the oceans to the continents each year. To complete the natural cycle, this water then makes its way back to the sea as runoff.

Viewed globally, fresh water is undeniably abundant and seems to defy notions of scarcity: The world's total renewable supply could support the material needs of five to ten times the existing world population. But these supplies are not always available where and when they are most needed. Moreover, unlike oil, metals, or wheat, water is not a global commodity—one that is easily traded internationally. If current trends continue, excessive water use in several of the world's major crop-producing regions may undermine the future capacity of the world to feed itself.

One-fifth of U.S. irrigated cropland is supported

by a water supply that is diminishing. For several decades, many farmers in the High Plains have irrigated their corn, sorghum, and cotton fields by pumping water from the Ogallala Aquifer, a vast underground reservoir stretching from southern South Dakota to northwest Texas. Much of the Ogallala's water is thousands of years old and gets little replenishment from rainfall. Over the last four decades, 132 trillion gallons have been withdrawn, and hydrologists estimate that the aquifer is now half depleted beneath large portions of Texas, New Mexico, and Kansas. As water tables fall, farmers faced with rising pumping costs and diminishing well yields are taking land out of irrigation. After nearly four decades of steady growth, the total irrigated area in the six states that rely most heavily on the Ogallala is now declining. Without a concerted effort to slow it, the Ogallala's depletion will continue. Much of this water is being used to grow crops of which the nation now has a surplus. When needed to meet vital future food needs domestically or abroad, this water may not be available.

Nearly half the irrigated area in the Soviet Union is located in the central Asian republics and Kazakhstan. Water supplies for the region come primarily from two rivers, the Amu-Dar'ya and the Syr-Dar'ya, and in dry years, virtually all the available water is used. These two rivers are also the main source of inflow to the Aral'skoye More (Aral Sea), helping to replenish the water lost to evaporation. Just as falling water levels are signaling water stress in the U.S. High Plains, the shrinking Aral'skoye More testifies to the shortage pending in central Asia: Heavy irrigation withdrawals from the Amu-Dar'ya and the Syr-Dar'ya have caused the sea's level to drop 29.5 feet since 1960, and its volume may be halved by the turn of the century.

In China, also among the world's three major grain producers, a water deficit is worsening in the northern provinces. The north China plain yields 25 to 30 percent of the value of China's crop output, besides supporting the large populations of Beijing and Tianjin. Groundwater pumping in the Beijing area now exceeds the sustainable supply by one-fourth, and water tables in some areas are falling as much as three to thirteen feet per year.

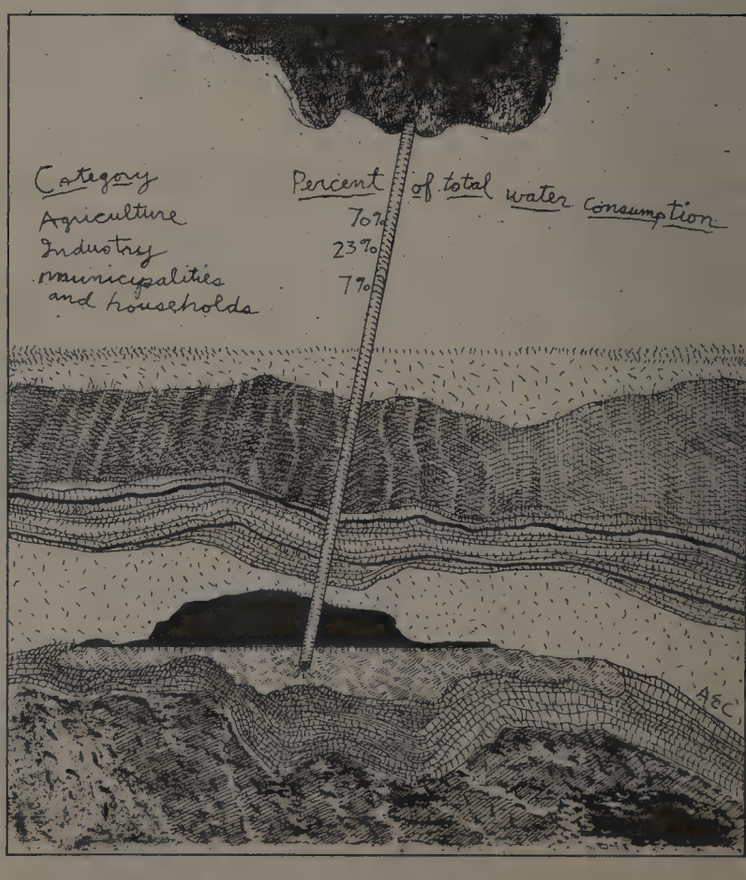
Historically, when natural water supplies became inadequate to meet a region's demands, water planners and engineers built dams to capture and store runoff that would otherwise flow through the water cycle "unused," and they diverted rivers to redistribute water from areas of lesser to greater need. Engineering feats, such as Egypt's Aswan Dam and the California Aqueduct, have literally made deserts bloom. But today many countries are finding that the list of possible dam and diversion sites is growing short and that the cost of developing new supplies is rapidly increasing.

China, the Soviet Union, and the United States have each examined large schemes for diverting water from a distant river basin to increase the supplies of their water-short agricultural regions. When the U.S. Army Corps of Engineers looked at the possibility of transferring water from midwestern rivers to the High Plains, it found that the costs were far higher than farmers would be willing to pay. Tight capital and $180-billion federal deficits are now forcing to an end the long era of massive water subsidies that allowed such uneconomical projects to materialize in the past. Consequently, prospects are dim that distant water will save irrigated agriculture atop the Ogallala.

Both China and the Soviet Union are proceeding cautiously with plans for river diversions unprecedented in scale. The Chinese have apparently begun construction on a 700-mile diversion of the Chang Jiang (Yangtze) River northward to the north China plain. The Soviets are preparing detailed engineering designs for a 1,500-mile diversion of north-flowing Siberian rivers south into central Asia. A final decision as to whether to proceed with construction—estimated to cost a daunting $41 billion—is expected in 1986. Yet even this grandiose scheme will meet only one-fourth of the water deficit projected for Soviet central Asia.

Thus far, water planners have paid little attention to the demand side of the water equation. But now that the economic and environmental costs of traditional supply-side strategies are becoming prohibitive, a fundamental shift toward reducing water demand offers the best prospect for alleviating water constraints.

Since agriculture claims the bulk of most na-



srael: The Thrifty Irrigator

Although the history of drip irrigation goes back to experiments in Germany in the 1860s, Israel pioneered the technology's commercial development during the last three decades. A drip system typically includes an extensive network of perforated plastic piping that is installed on or below the soil surface. Because water is delivered more directly to the crop's root zone, less water evaporates and is lost from the field. Another advantage is that soluble fertilizer can be added directly to the irrigation water, thereby cutting the amount of chemicals spread over the field and lessening the chance of groundwater contamination. With plants receiving optimum amounts of water and nutrients, crop yields can increase. Experiments with drip in Israel's Negev Desert have shown per acre yield increases of 80 percent over sprinkler systems.

Israel also pioneered the development of automated irrigation, in which the timing and amount of water applied are controlled by computers. The computer not only sets the water flow; it also detects leaks, adjusts water application for wind speed and soil moisture, and optimizes fertilizer use. Motorola Israel Ltd., the main local marketer of automated systems, recently began exporting its product; by 1982 more than 100 units had been sold in the United States. Israel's overall gains in agricultural water-use efficiency, through widespread adoption of sprinkler and drip systems and optimum management practices are impressive: The average volume of water applied per acre declined by a fifth between 1967 and 1981, allowing the nation's irrigated area to expand by 39 percent while farmers' water withdrawals grew by only 13 percent.—*S.P.*

tions' water budgets—and 70 percent of water withdrawals worldwide—saving even a small fraction of this water frees a large amount to meet other needs. Raising irrigation efficiencies worldwide by just 10 percent, for example, would save enough water to supply all global residential water uses. Vast quantities of irrigation water seep through unlined canals while in transit to farmers' fields, and much more water is typically applied to crops than is necessary for them to grow. Even in a technologically advanced nation such as the United States, irrigation efficiencies are often less than 50 percent.

Most farmers irrigate their fields with gravity-flow systems, the oldest method and generally the least expensive to install. Water seeps into the soil as it flows across a gently sloping, sometimes furrowed field. Without careful management, a large share often percolates to great depths or runs off the field. Only a small portion remains in the root zone, where the crops can use it. Sprinkler systems, which come in many varieties, deliver water in a spray. They are typically more efficient than gravity systems, but since they operate under pressure, they require much more energy. One design—the center-pivot system—was largely responsible for the rapid expansion of irrigation on the U.S. High Plains in recent decades. Drip irrigation systems release water close to the plant's roots, thereby minimizing evaporation and seepage losses. Although expensive, carefully designed and operated drip methods often use 30 to 50 percent less water than conventional gravity systems.

With the exception of countries such as Israel, which is already using 95 percent of its freshwater supplies, most governments still treat water as a limitless resource. U.S. farmers supplied with irrigation water from federal projects, for example, pay on average less than one-fifth of the real cost of supplying it. Taxpayers are burdened with the remainder, and farmers have little incentive to adopt water-conserving irrigation methods.

But at least one example worth emulating has emerged in the United States: the 1980 Arizona Groundwater Management Act. Facing a rapidly dwindling groundwater supply, Arizona is requiring its most overpumped areas—including Tucson and Phoenix—to achieve "safe yield" by the year 2025. At this level, no more groundwater is withdrawn than is recharged; the resource is thus in balance. Conservation measures will be required of all water users and all groundwater pumping will be taxed. If, by the year 2006, it appears that conservation alone will not achieve the state's goal, the government can begin buying and retiring farmland. The state's water supplies simply cannot support both a booming population and a water-thirsty farming economy for long.

Although agriculture is the biggest water consumer, conservation in cities can greatly reduce the cost of pumping and treating household water, besides delaying the need to develop more costly supplies. Several states, including California, Florida, Michigan, and New York, now have laws requiring the installation of various water-efficient appliances in new homes, apartments, and offices. A 1983 California law also requires every urban water supplier in the state to submit by the end of 1985 a management plan that explicitly evaluates efficiency measures as alternatives to developing new supplies.

In an era of growing competition for limited water sources, heightened environmental awareness, and scarce and costly capital, new water strategies are needed. Alternatives to large dam and diversion projects exist, and water crises need not occur. Failing to take steps toward a water-efficient economy is risky: Future food needs may go unmet, industrial activity may slow, and the rationing of drinking-water supplies may become more commonplace. Conservation and better management can free a large volume of water—and capital—for competing uses. Thus far, we have seen only hints of their potential.

Sandra Postel

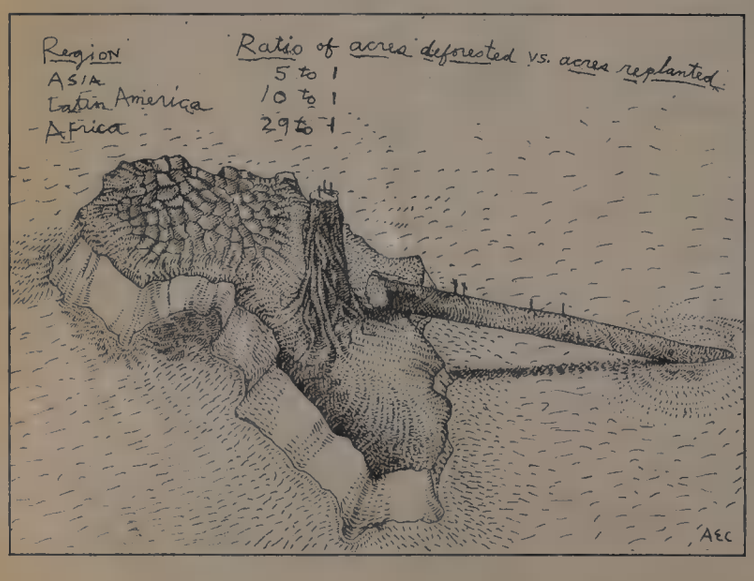
The earth's forest systems are collapsing under two different sets

of pressures; in the tropics, 76,000 acres of trees are cleared daily—an annual loss of forested area nearly the size of Pennsylvania. And in the northern tier of industrial countries, damage linked to air pollutants or acid rain affects trees covering more than 12 million acres—an area the size of New Jersey and Maryland combined.

Wooded lands of all types cover 12 billion acres, an area more than triple that in crops. Tropical America, Africa, and Asia account for 60 percent of the total, and it is in these regions that large-scale clearing of forests is taking place. Unabated population growth is causing conversion of forest to cropland as more and more rural families try to survive on increasingly marginal land. Some replacement of trees with crops is clearly essential to increase food production, but the tragedy in the tropics is that forests are often cleared either where soils are too infertile to sustain crop production over the long term or in a manner that prematurely depletes the land's productive capacity.

Shifting cultivation, which for centuries provided a sustainable agricultural system, has broken down with the population buildup of recent times. Traditionally, farmers would clear some forest, grow crops until the soil became too deficient in nutrients, and then clear a new area, returning to the original plot perhaps twenty years later. By then, the land had lain fallow long enough to restore its fertility. But in many areas, population densities no longer allow for the twenty-five to fifty acres of land per person needed to sustain this farming system. The land is overused, additional forests are cleared on soils that cannot sustain crops, and destruction spreads.

Fuelwood gathering, timber harvesting, and in Central America, conversion of forest to pasture are other forces behind deforestation. As forests dwindle, signs of scarcity grow, taking an especially large toll on the third of humanity for which firewood is the only source of cooking fuel and warmth. In many west African and Central American towns and cities, a typical family may spend one-quarter of its earnings on fuelwood and charcoal, comparable to what a family in an affluent society might spend on housing.



According to the United Nations Food and Agriculture Organization (FAO), more than 100 million people—half of them in Africa—cannot get enough fuelwood to meet their basic needs. Nearly 1.2 billion people are meeting their needs only by overcutting and depleting their forest resources, an unsustainable practice. FAO projects that by the year 2000, more than half the people of the developing world will be in one of two categories—either lacking sufficient firewood or meeting their needs by depleting the resource.

Rarely valued monetarily, the loss of the ecosystem services provided freely by a natural forest entails real economic and social costs. An intact forest moderates the water cycle, allowing rainwater to infiltrate the soil. Especially in regions subject to the extremes of a monsoon climate, deforestation and the loss of this buffering effect worsen flooding, drought, and soil erosion. The cost of repairing flood damages in India below the Himalayan watershed has recently averaged $250 million per year. In the Philippines, a government report blamed deforestation for frequent flooding, erosion, river siltation, and a loss of water supplies. Silting of the reservoir behind Ambuklao Dam has halved the hydropower plant's useful life.

Putting forestry on a sustainable footing in the Third World requires addressing deforestation's underlying causes: excessive population growth, landlessness, and the shortage of productive livelihoods for the rural poor. Recently, some projects have made forestry more responsive to people's needs. In the Indian state of Gujarat, the government has offered free seedlings to farmers, and tree farming is providing a stable source of income. Another approach, agroforestry, integrates tree and crop plantings for combined fuel and food production. In the Kordofan region of Sudan, where desertification and firewood shortages are severe, efforts have focused on restoring the traditional practice of growing nitrogen-fixing acacia trees along with food crops.

China and South Korea have each mounted national tree-planting campaigns to reclaim vast areas of degraded land. China's official goals are to increase its forest cover from 12 percent to 20 percent by the year 2000 and ultimately restore trees to one-third of its territory. South Korea had rapid success with a replanting program begun in the

It comes with a conscience.

Honda has always made good cars. People love them. But with any loved one, things can sometimes get emotional.

Honda understands. And on our own we have set up a third-party arbitration program with the Better Business Bureau to give you an extra voice, if you need it.

But please talk with your dealer first. And follow the problem-solving procedure described in your owner's manual.

Our new program will help to resolve product-related questions about your Honda. This program is free. Just ask at any Honda dealer for a booklet containing more information.

Or call 800-521-1613. You see, Honda wants you and your Honda to have a long and happy relationship. It's only right.

Our vacations last for years.

How much do you remember about your last vacation?

Did every moment of it, every discovery, every delight etch itself indelibly into your mind?

A vacation should, you know.

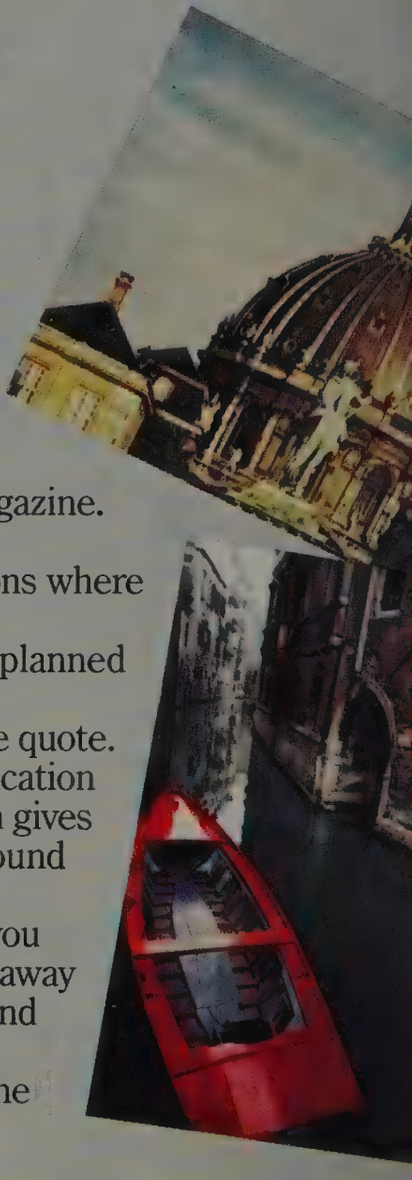
At TWA Getaway®, we have 113 unforgettable vacations to some 28 countries in Europe and the Middle East. To begin to describe all there is to find on even one of them would fill this magazine.

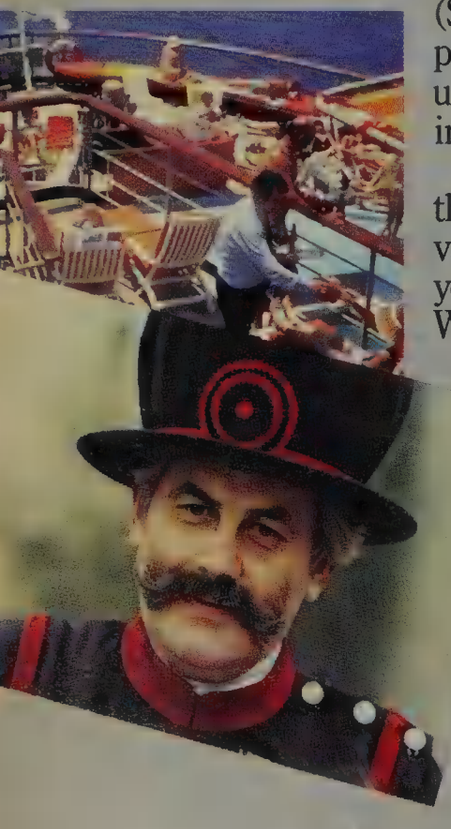
There are, of course, our brochures.

In them, you'll see escorted tours. Cruises. Freestyle vacations where you're free to wander on your own.

You'll note that our hotels are run attentively. Our itineraries planned out thoughtfully. Our guides selected carefully.

You will wonder how we're able to pull this off at the prices we quote. (Simple answer. TWA Getaway is the leading vacation packager to Europe and the Middle East. Which gives us a considerable amount of weight to throw around in the buying-power department.)





You will even see a warranty, and it will tell you that should even the smallest part of a TWA Getaway vacation fail to deliver on its promises, we'll refund you for it.

What you won't see, however, is the sparkle of the water of the Grand Canal in Venice as you glide along it.

You won't feel what it's like to stand before a place where civilization was born.

You won't experience the infectious warmth of an out-of-the-way Alpine Gasthaus.

But you will find one of the best ways to do that, and more.

See your travel agent or call 1-800-G-E-T-A-W-A-Y.

TWA Getaway vacations. Memories are made of this.

TWA GETAWAY VACATIONS

LEADING THE WAY.sm

early seventies. In just a few years, trees were established on an area more than half that in rice, the country's food staple.

Unfortunately, the political will and commitment of resources needed to break the cycle fostered by deforestation is lacking in much of the tropical Third World. At present, only one acre of trees is planted for every ten acres cleared. The gap is greatest by far in Africa, where the ratio of tree clearing to planting is twenty-nine to one. Meeting the Third World's projected fuelwood needs by 2000 would require a thirteenfold increase in the current rate of tree planting for nonindustrial uses.

While lack of economic progress drives deforestation in the Third World, the byproducts of industrialization are threatening forests in the temperate zone. In the past decade, it has become evident that air pollutants from the combustion of fossil fuels—both oil and coal—and the smelting of metallic ores are undermining sensitive forests and soils. Many forests in Europe and North America now receive thirty times more acidity than they would if rain and snow were falling through a pristine atmosphere. Ozone levels in many rural areas of Europe and North America are now regularly in the range known to damage trees. Acting alone or together, several pollutants—including acid-forming sulfates and nitrates, gaseous sulfur dioxide, ozone, and heavy metals—are placing forests under severe stress. Needles and leaves yellow and drop prematurely from branches, tree crowns progressively thin, and ultimately, trees die. Even trees that show no visible sign of damage may be declining in growth and productivity.

In just a few years, forest damage has spread with frightening rapidity through portions of central Europe. No nation has better documented the destruction within its borders than West Germany, where forests cover roughly a third of the land area. The government's most recent survey shows that half the nation's trees are injured, and so far the destruction shows no signs of abating. (See box.) A total of 2.4 million acres are affected in Poland and Czechoslovakia. Environmental scientists have warned that by 1990 more than 7 million acres of Poland's forests may be lost if the nation proceeds with its present industrialization plans, which call for increased burning of the nation's high-sulfur brown coals.

Damage reported in other European countries, including Austria, Switzerland, the Netherlands, East Germany, Romania, and Sweden, adds to the growing evidence of unprecedented forest devastation. In the United States, from the Appalachians of Virginia and West Virginia northward to the Green Mountains and White Mountains of New England, red spruce is undergoing a serious dieback—a progressive thinning from the outer tree crown inward. Damage is most severe in the high-elevation forests of New England. By the spring of 1984, researchers had detected serious spruce damage as far south as North Carolina's Mount Mitchell—the highest peak in eastern North America—and tree deaths were expected to be identified in other areas soon thereafter.

Recent publicity about acid rain has tended to lump this forest destruction with acidifying lakes, dying fish, and other effects of acid rain. Forest damage has added impetus to calls to reduce emissions of sulfur dioxide, the primary acid rain precursor. Indeed, fifteen European countries and Canada have made formal commitments to reduce sulfur emissions by 30 percent or more by the early nineties; notably absent from this "30 percent club"

West Germany: Death of a Fairy Tale Forest

West Germany's forests are not just sources of lumber and pulp—they helped shape the nation's cultural and literary heritage. The loss of these woodlands is a potent political and emotional issue for West Germans. *Waldsterben*—or forest death—is now a household word. A survey in the summer of 1983 showed that West Germans were more concerned about the fate of their forests than about the Pershing missiles to be placed on their land later that year.

Following a 1982 forest survey, the federal minister of food, agriculture, and forestry estimated that 8 percent of West Germany's forested area was damaged. Just a year later, a more thorough investigation found damage on more than 6.2 million acres—34 percent of the nation's forests. A third survey, conducted in the summer of 1984 and the latest to date, found that half the nation's trees are injured. Hardest hit are the heavily wooded states of Bavaria and Baden Württemberg, home of the fabled Black Forest.

Spruce, fir, and pine, which together represent two-thirds of West Germany's forests, are the most severely struck. The spruce and fir forests are typically managed in even-aged stands, with trees harvested between 80 and 130 years of age. Although damage first appeared on the older trees, spruce and fir of all ages are now affected. The value of the trees already lost exceeds $1.2 billion. Because a growing portion of the planned annual harvest consists of dying trees, the harvest may reach three times its normal level over the next few years. Although this may depress timber prices over the short term, future supplies are diminishing as sick and dying trees are harvested long before their time.

In a 1983 *Journal of Forestry* editorial, a German professor of forest policy, the president of the German Forestry Association, a Regensburg forester, and a former U.S. Fulbright visitor to West Germany joined together to note that "air pollution is now the problem that concerns West German foresters most. The results of 200 years of forest management seem to be extinguishable within the next 10 years. . . . Only a few people think about an all-too-possible scenario: central Europe without forests."—*S.P.*

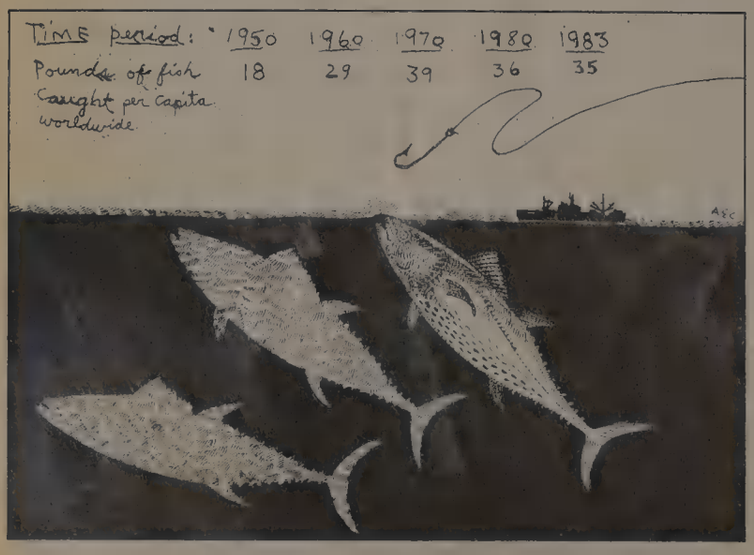
are the United States and Great Britain. While putting scrubbers on smokestacks is a necessary first step to curb acid rain in the near term, a technological fix for one pollutant cannot be an ultimate solution for a multipollutant problem. Solutions are needed that will reduce levels of all threatening pollutants. Using energy more efficiently, recycling more paper and metals, and generating more power from alternative energy sources are rarely considered in strategies to control air pollutants or acid rain, but they are perhaps the most cost-effective ways that exist.

Given the rapidity with which the forest destruction has unfolded, the relevant question is no longer whether proof of damage from air pollutants or acid rain is irrefutable but whether the forests are sufficiently threatened to warrant action. West German foresters would answer with an unequivocal yes. But the real test is whether nations that so far have been spared severe losses will muster the political will to take action to avoid them.

Sandra Postel

Overfishing was rare a generation ago. Now, in some regions it seems

to be a common occurrence. The world's fisheries occupy an important niche in the global ecosystem, the world economy, and the human diet. Their annual harvest—74 million tons in 1983—exceeds world beef production by a substantial margin. Yielding an average of thirty-five pounds per person worldwide, fisheries supply 23 percent of all animal protein consumed. More importantly, in many low-income countries, as well as in a few industrial ones, fish are the principal source of animal protein.



Between 1950 and 1970, the world fish catch more than tripled. The growing world population and rising per capita incomes boosted demand for animal protein. The extraordinary growth in the catch led to the feeling that the oceans contained infinite supplies of fish. Projections made at this time commonly indicated the catch would eventually reach 200 to 400 million tons annually. On the supply side, advances in fishing technology and the availability of cheap oil led to the development of distant-water fishing fleets that scoured the oceans in search of edible sea life.

By the early seventies, however, many signs of overfishing were appearing. Growth in the annual world fish catch slowed to less than one percent. And in per capita terms, the growth of nearly 4 percent per year during the fifties and sixties became a decline of almost one percent yearly after 1970.

The collapse of the Southeast Pacific anchovy fishery in the early seventies, caused by overfishing and ocean variability, caught the attention of many who had assumed that humanity would ultimately turn to the oceans for food. By the early eighties, eleven major oceanic fisheries—six in the Atlantic and five in the Pacific—had been depleted to the point of collapse. They range from the Peruvian anchovy, which had an estimated potential of 9 million tons, to the Alaska king crab, with a possible yield of nearly 100,000 tons. Overall, the annual harvest from oceanic fisheries has been reduced by an estimated 11 million tons because of fishery mismanagement.

Before national control was extended to 200 miles offshore, there was often no authority responsible for limiting the catch and establishing quotas for the fleets working a fishery. In some cases, overfishing resulted from a lack of information—on such things as stocks and reproductive rates—needed to manage supplies intelligently. As the biology of oceanic fisheries becomes better understood, a concern for sustainable yield is likely to dispel the myth that the oceans can provide an ever increasing supply of protein.

More than one hundred species of finfish, crustaceans, and shellfish are harvested on a commercial scale. Of this long list, some twenty-two species commonly yield 100,000 tons or more per year, and just five species—herrings, cods, jacks, redfishes, and mackerels, plus their associated relatives—account for well over half the annual catch.

The diversity of the global catch is reflected in national seafood consumption patterns. In the United States, tuna occupies a prominent position in overall seafood consumption: With tuna sandwiches and salads common fare, U.S consumption accounts for more than a third of the world tuna catch. Of the million and a half tons of squid caught yearly, most is consumed by Japan and the coun-

tries north of the Mediterranean—Spain, Portugal, and Italy. The consumption of some other abundant species is similarly concentrated in parts of the industrialized world.

Although per capita fish consumption in Third World countries is lower than in most industrial countries, fish are nonetheless a key protein source in the diet of coastal peoples. A scrap of dried fish in a rice dish can often mean the difference between a nutritionally adequate diet and one seriously deficient in protein. The worldwide decline in the per capita catch does not augur well for future nutritional improvements in developing countries.

With oceanic overfishing now commonplace, the age-old method of capturing fish by hunting and gathering is being supplemented by fish farming and ranching. In many parts of the world, fish can be raised like livestock using natural ponds or artificially flooded land. The many techniques, collectively known as aquaculture, succeed with a variety of fish and shellfish. Harvesting can be done on a small or a large scale and can often be integrated with conventional farming, using organic wastes from land to fertilize ponds and provide a food supply for fish.

Fish farming is growing at more than 7 percent each year, and cultivated fish may be the fastest-growing part of the human diet. Interest in fish farming is on the rise everywhere. China, with an estimated annual aquacultural output of just over 4 million tons, is far and away the world leader. Japan ranks second, with about a million tons—roughly one-third each of finfish, shellfish, and seaweed. Given the rapid strides in U.S. fish farming during the early eighties, a 1985 survey is likely to show the United States moving into the top ten aquacultural producers.

A growing emphasis on this approach is evident in the lending practices of such international aid agencies as the World Bank and the U.N. Food and Agriculture Organization. In the seventies, assistance that previously concentrated on investments in better boats and improved port and processing facilities shifted toward fish farming. Lenders realized that there were a limited number of offshore fisheries in which investment in additional capacity would be profitable.

Worldwide, aquaculture provides roughly one-sixth of the seafood consumed directly. Of the total finfish output of some 3.7 million tons, an estimated four-fifths is accounted for by carp, the mainstay of both the Chinese and Indian aquacultural economies. In both these countries, the aquacultural sector provides more than one-fourth of total fish consumption. In the United States, nearly all the rainbow trout, most of the catfish and crawfish, and 40 percent of the oysters are harvested from fish farms.

One of the attractions of fish farming is the high efficiency with which fish convert vegetable matter to meat. An American farmer must feed his cattle roughly 7 pounds of grain to produce a pound of beef. Pigs, by comparison, need 3.25 pounds of grain to yield a pound of pork; broilers need 2.25 pounds for a pound of chicken. Catfish, however, require only 1.7 pounds of grain to produce a pound of fish. Fish are efficient converters for two reasons. One, they are coldblooded and thus do not need to consume large amounts of energy to maintain a high and steady body temperature. And two, because they live in the water, fish do not require much energy for locomotion.

That fish farming is destined to expand seems clear; how fast it will do so is less certain. As a form of animal husbandry, it must compete with the production of beef, pork, poultry, eggs, and milk for

Salmon at Home on the Ranch

In past times, salmon apparently thrived in streams and rivers throughout the Northern Hemisphere's higher latitudes. With modernization, however, their access to many streams and rivers was often blocked by dams, as in the U.S. Pacific Northwest and in the Baltic Sea. Some rivers—such as the Thames in England, where the salmon disappeared in the nineteenth century—became so polluted that they were no longer habitable. In other instances, merciless overfishing led to the salmon's demise.

In recent years, a better understanding of the salmon's life cycle and a strong commercial demand for this tasty fish have led to the restocking of many streams. In 1763, German biologists discovered that salmon eggs could be fertilized in captivity. This knowledge, coupled with an awareness of the salmon's homing instinct, set the stage for modern ranching. Salmon hatcheries (usually publicly supported) and commercial salmon ranching are both based on the near-legendary homing instinct of this fish. Even when released in an unfamiliar setting, salmon manage to find their way back to their nursery streams some two to five years later when it's time to breed.

The only countries with extensive salmon hatcheries and annual releases of this fish are Japan, the Soviet Union, and the United States. The Japanese now release more than a billion young salmon each year in rivers and streams on the islands of Hokkaido and Honshu. After feeding in the areas south of the Bering Sea, the Aleutian Islands, and the Gulf of Alaska, the salmon return to the rivers where they were released. In the fall of 1982, the Japanese harvested 28 million salmon—one for every four Japanese. Soviet salmon ranchers are not far behind: They are expanding the number of smolts released by roughly 100 million per year, and their goal is to release 3 billion annually by the end of the century. The Soviet salmon are released in the many small streams of Sakhalin Island and the Kamchatka Peninsula. By 1990, the USSR, Japan, and the United States are expeted to release 6 billion smolts into the North Pacific.—*L.R.B.*

the use of land, water, labor, fertilizer, and feedstuffs. But in a world where pressure on resources is mounting, aquaculture should also be seen as a means of tapping currently unused resources, such as low-lying land that is not suitable for crop production.

With mounting pressures on world fisheries—oceanic and domestic—fishery analysts see seafood prices rising for the rest of the century and beyond. This may annoy Western consumers for whom salmon or Alaskan king crab is a delicacy. But it will be much more than annoying for those in the Third World for whom fish is the principal source of animal protein.

Lester R. Brown

Is human activity causing global climate changes? Until recently,

the question has rightly focused on fossil fuels and carbon dioxide (CO_2). In step with the burning of oil, coal, and natural gas, the concentration of CO_2 in the atmosphere has steadily climbed. Climatologists warn that increased CO_2 traps more of the sun's heat at the earth's surface; the implications of this "greenhouse effect" have put climate change at the center of a lively political and scientific debate.

Recently another question has emerged: Can changes in land cover, such as deforestation in the Third World, alter climate? The contribution of population growth to deforestation, overgrazing, soil erosion, and desertification in the Third World is highly visible and widely recognized. What is new is the realization that these processes may be driving climate changes in regions as diverse as the semiarid Sudan-Sahelian zone of Africa and the rain forests of the Amazon.

Natural climatic fluctuations make it difficult to separate out the possible human effects on climate. A reconstructed climatic history of the Sahel over the last 10,000 years, for example, shows extreme fluctuations, from periods of wetness to dryness. A detailed history of just the last few centuries shows that the Sahel has periodically experienced severe, prolonged drought.

Meteorologists have traditionally dismissed the notion of large-scale human-induced climate change, arguing that the natural forces driving global atmospheric circulation would override any local, human-induced alterations. Using data from other fields, such as agriculture, ecology, and hydrology, meteorologists can now piece together a plausible hypothesis that population-induced local climatic change is indeed under way in Africa, the Amazon Basin, and perhaps elsewhere as well.

The continents are watered by the oceans; therefore, any change induced by population growth must involve interfering with the mechanics of that process. Africa, for example, is watered by moisture-laden air masses from the Indian and Atlantic oceans. The Indian subcontinent receives rain from clouds moving inland from the Indian Ocean and the Bay of Bengal. The Brazilian Amazon derives almost all its water initially from the Atlantic Ocean.

Evaporation of moisture from rainfall near the coasts recharges rain clouds as they move inland. At a typical site in the central Amazon, such as one that was carefully studied near Manaus, Brazil, roughly one-fourth of the rainfall evaporates directly, and nearly one-half reenters the atmosphere in the form of transpiration from plants. Together, direct evaporation and transpiration return three-fourths of the rainfall to the atmosphere, leaving one-fourth as runoff that makes its way back to the Atlantic. Such high levels of cloud recharge have led ecologists to refer to tropical rain forests as "rain machines."

When land is deforested, however, this ratio is roughly reversed, with a quarter of the rainfall being returned to the atmosphere and three-quarters running off quickly. Rainfall in the region is accordingly reduced, as the atmosphere holds less returned moisture that can become rain later in the cycle. The more distant from the coast, the more an area depends on evaporation for the recharge of rain clouds. Even in semiarid regions, an estimated one-third to two-thirds of all rainfall comes from soil moisture evaporation.

Water first enters the Amazon area in moisture-laden air masses from the Atlantic Ocean. As these progress westward, they continually discharge moisture in the form of rain and are recharged by evaporation and transpiration. On the average, water in the Amazon that does not return to the ocean completes the cycle every 5.5 days. During this process some of the water works its way out of the evaporative cycle as runoff and begins the long trip back to the Atlantic. Moisture left in the air when it reaches the Andes moves southward into central Brazil and the Chaco/Paraguay river regions, where it becomes part of the rainfall cycle in major farming areas.

As the Amazon rain forest is converted to cropland or grassland or is cleared by logging, the share of rainfall that runs off increases. The proportion that returns to the atmosphere through evaporation falls, reducing the total amount of water in the area's hydrological cycle. The net effect is lower average rainfall, particularly in the west. Less rain in

A lifetime of emotions wrapped up in one word:

Cancer

Let's keep our heads. It is tremendously important that everyone know what cancer is. And what it is not. Cancer is not one disease. Some cancers may be prevented by good health habits. Some are easy to control; others may be severe or life-threatening. Different cancers are subject to different treatments. Most important of all, it is imperative to know that cancer need NOT be fatal.

Here is the latest news about cancer:
One of the leading scientific journals, *Nature,* recently said, "1983 may be the year in which carcinogenesis is finally understood."

Some of the best informed scientists in the world say that we may see substantial control and cure of cancers before this century is over. By the year 2000, the incidence of total cancers should be markedly decreased by prevention and cure. This is believed because of the rapid advances in the past several years, and what we can surely anticipate in the years just ahead.

The attack on the problem of cancer is vast, here and the world over. Scientists in universities, pharmaceutical organizations and government health agencies are coordinating activities that are supported by huge budgets and by an immense technology. A tremendous body of experience has been amassed for many different cancers.

Too much fear can be dangerous.
Early diagnosis is essential to arrest and to overcome many cancers. But early diagnosis is often hindered by fear. And fear is worse when one does not know the facts. Here are simple all-important facts: Cancer is NOT the commonest cause of death. Many cancers are curable.

Too often fear delays treatment. The best way to overcome fear is to get all the facts. More often than not, your fear that you have cancer will prove to be wrong. But it is still absolutely essential that you get a medical examination and that your doctor (not you, nor your family, nor your friends) make a diagnosis.

Fear that someone in your family has cancer should also be promptly addressed. Here again, seek the advice of your physician. There are also many qualified professionals and special organizations that provide information on cancer in virtually every major community in the United States.

Remember, knowledge is the best cure for UNFOUNDED fears.

Hope is the key to the future.
Hope is what the latest facts and figures on cancer are all about.
Hope resides in early diagnosis.
Hope resides in early treatment.
Hope resides in current research.

We now know that cancer can be diagnosed and treated with an array of new technology and knowledge. You are not alone in preventing or treating cancer. You need and have a support system. We call it...

Partners in Healthcare:

You are the most important partner.
Only you can take the first step. And at the first warning sign—a lump, unusual bleeding from any part of the body, a sore that does not heal, an obvious change in a wart or mole, a nagging cough or hoarseness, a change in bowel habits—DO NOT WAIT. CONSULT YOUR PHYSICIAN AT ONCE.

Your doctor interprets the warning signs, orders your tests and makes the diagnosis.
The chances are that your physician will find something other than cancer. But it is essential that, whatever tests are needed, they be done quickly for an early diagnosis.

All those who discover, develop and distribute medicines complete the partnership.
Pharmaceutical companies in the past few years have developed many good drugs for cancers. We at Pfizer are fulfilling our role as one of your partners in healthcare by mobilizing our doctors, chemists, technicians, a huge range of facilities and modern instrumentation to do our share in the search for the cause and the ultimate cure of cancer and other diseases.

For a copy of the pamphlet The Hopeful Side of Cancer, *write to the American Cancer Society, G.P.O. Box 1400, Dept. 2012, New York, N Y 10116.*

For reprints of this Healthcare Series, please write: Pfizer Pharmaceuticals, Post Office Box 3852, Grand Central Station, New York, NY 10163.

PHARMACEUTICALS • A PARTNER IN HEALTHCARE

THE HIGH-PERFORMANCE VEHICLE
THE SAME KIND OF BRAKING SYSTEM

THE LEFT NOW USES HE ONE ON THE RIGHT.

Somewhere at this moment a jet aircraft carrying several hundred passengers is touching down at triple-digit speeds.

On runways whose surfaces could be perfectly dry, or dotted with icy patches, or glazed with rainwater.

It is about to perform the single most important act any moving vehicle ever performs: the act of stopping.

That feat is no less important when performed on behalf of one to five passengers in a BMW, which, besides roads and weather, must also contend with the treacheries of traffic.

That's why both vehicles use "what is considered by many to be the biggest advance in braking since the disc" (AutoWeek)—the anti-lock braking system (ABS).

STEER AND STOP AT THE SAME TIME.

On the BMW, as on the aircraft, electronic sensors measure the rotational speed of the wheels, feeding this data to a computer. (The computer is well fed; we use four sensors as against a competitor's three.)

Then, operating on the computer's command, a hydraulic control unit applies braking pressure as it should be applied: in the rapid pumping movements that prevent the brakes from locking.

And it does so faster than humanly possible, even if the human in question is a Grand Prix driver. An experienced race driver might be able to pump four times a second; our ABS system, ten.

Should any wheel begin to lock, the computer instantaneously reduces braking pressure until control is regained. A vital factor in panic stops, where both wheels and driver freeze, placing the car at the mercy of its own momentum. ABS permits you to steer and stop at the same time.

ABS is new, and standard, on the BMW 735i, 635CSi and 535i. But in the ways that matter most, it isn't new at all, having proven itself not just on airborne vehicles, but their landborne equivalents: BMW race cars dating back over a decade.

A SYSTEM, NOT AN AFTERTHOUGHT.

ABS arrives not as an addendum or afterthought but as part of a larger system devoted to maximizing your control over the vehicle.

For example, ABS matches, and is fully justified by, BMW's new 3.5-liter fuel-injected engine—a zealous power plant whose talents for acceleration are ideally counterbalanced by ABS's skills in deceleration.

It is also a perfectly compatible mate to BMW's fully-independent suspension systems, with which it shares a common birthplace: high-speed racecourses, where issues of agility and precision take on a special urgency.

All that sets the BMW apart from every other luxury car in the world—but also gives it some vital common ground with the other high-performance vehicle shown (in part) here:

The recognition that true performance isn't measured just by how fast a vehicle goes, but by how well it stops—and how well it does everything in between.

THE ULTIMATE DRIVING MACHINE.

the Amazon would almost certainly reduce the amount that reaches the agriculturally important Paraguayan Chaco and central Brazilian plateau.

In Africa, northeastern Brazil, northwestern India, and northwestern China—where rapidly growing populations are generating wholesale shifts in land use—deserts are expanding. Recently the United Nations Environment Programme undertook a survey of desertification in countries in the Sudan-Sahelian region of Africa. The fourteen most populous countries in this group have a combined population of 230 million people, 43 percent of the African total. The survey focused on five manifestations of desertification—sand dune encroachment, rangeland deterioration, forest depletion, the deterioration of irrigation systems, and problems in rainfed agriculture.

Not one of the seventy indicators—five for each of the fourteen countries—showed any improvement. According to thirteen of the seventy indicators, there was no significant change during the seven years under review. Half the total measurements showed moderate deterioration. The remaining twenty-one showed serious deterioration. The three categories showing the most consistent deterioration were rangelands, forests, and rainfed agriculture. Field observers confirm the survey findings, describing them as somber but realistic.

Perhaps because of the Sahelian drought of the early seventies and the continent-wide drought experienced in Africa in 1983 and 1984, more attention has been focused on changing land-use patterns caused by population pressure and the possible effects on local climate. In addition to the evidence from agriculture and meteorology, and the desertification trends, hydrological data also suggest that Africa is "drying out." In an analysis measuring changes in river flows, J. Sircoulon observes that "the Senegal, Niger, and Chari rivers, coming from wetter regions to the south . . . have undergone a severe decrease of runoff during the last 15 years. . . . Lake Chad has shown a systematic decrease of level since 1963. At that time the lake's surface covered 23,500 square kilometers, and the volume of stored water was 105 billion cubic meters. In 1973 the surface had been divided by three and the volume by four. Since this date, the lake has been cut into two parts. The northern part dries up every year, with only a small inflow through the 'Grande Barrière.' "

Most meteorologists have been reluctant to attribute significant shifts in climate to human changes in land use. Although the evidence that can now be assembled from several fields of study is not yet conclusive, it is persuasive. Reflecting on this, Canadian meteorologist Kenneth Hare, in an analysis of desertification in Africa, has concluded that "we seem to have arrived at a critical moment in the history of mankind's relation to climate. For the first time we may be on the threshold of man-induced climatic change."

Knowing what we do about the extent of deforestation, overgrazing, and soil degradation during the past generation and about the way the hydrological cycle works, we should not be surprised by changing climate. More significantly, population growth may be driving that change in directions that will not benefit the people affected, reducing rainfall in areas where rain is needed for crop production and livestock grazing. And expanding deserts, in turn, are shrinking the land area available for growing food, grazing livestock, and producing firewood. The effectiveness—or ineffectiveness—of family planning programs may be shaping the climate of some countries for decades and possibly for centuries to come.

Lester R. Brown

The failure to eliminate human hunger weighs heavily on the collective

conscience, dimming the numerous remarkable achievements of the late twentieth century. From about 1950 to 1973, world food production surged ahead, outstripping population growth and holding out the hope that hunger could be banished. In the last decade, however, growth in production has slowed, raising doubts about the long-term food

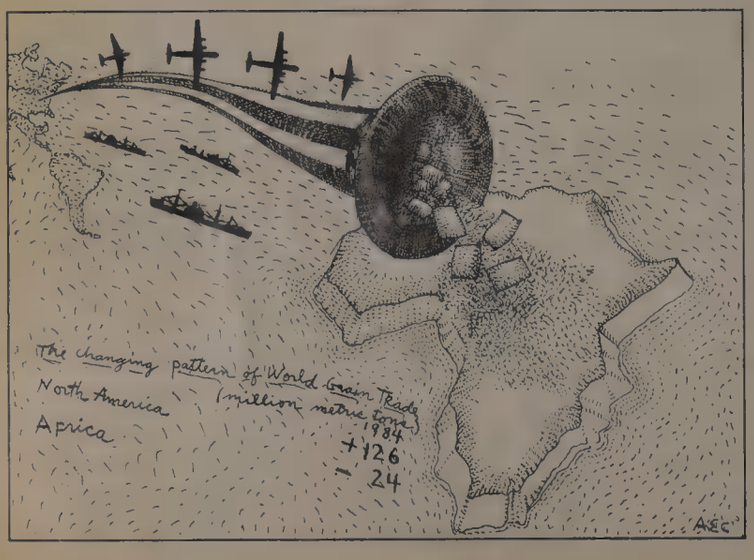
prospect. Despite advances in technology, the effort to reduce hunger is at a standstill.

The shifting contours of the world food economy are dominated by two major developments. One is the leveling off of per capita food production since 1973, following a quarter-century of steady gains. The other, obscured by this global trend, is the growing food gap between country and country, continent and continent. In some regions, per capita food production is surging ahead; in others it is falling steadily.

From 1950 to 1973, the year of the first oil price hike, world grain output expanded more than 3 percent annually, boosting per capita output by some 30 percent. Since then it has averaged only 2 percent yearly, barely keeping pace with population growth. Tightening supplies of energy, land, and water are now shaping the world food prospect.

From the beginning of agriculture until roughly mid-century, the expansion of the world's cropland area more or less matched the growth in world population. The supply of food increased from year to year largely because the total cultivated area was expanding. But improvements in productivity per acre came slowly or not at all. At mid-century, this began to change. Since then most of the growth has come from boosting land productivity. Growth in the cropland area has continued to slow, coming to a standstill in some countries. Between 1980 and 2000 the world cropland base is projected to expand by only 4 percent, while the world's population is projected to expand by some 40 percent.

In recent decades, much cropland has been lost to industrialization and to urbanization, the latter being one of the most globally pervasive demographic trends of this century. How much cropland is disappearing under cities is not known, but various surveys and data from individual countries provide some indication. For example, U.S. Department of Agriculture surveys in 1967 and 1975 indicated that some 6.2 million acres of prime U.S. cropland were converted to urban uses during the eight-year period. A study of urban encroachment on agricultural land in Europe (grasslands as well as croplands) from 1960 to 1970 found that West Germany was losing one percent of its agricultural land every four years. For France and the United Kingdom, the comparable figure was nearly 2 percent for the decade.



While attention has focused on urban encroachment, cropland is also being lost to village expansion. Unfortunately, little research has been conducted on this loss. Using data gathered during several decades in his native Bangladesh, Akef Quazi concludes that growth of the area occupied by a village and growth in the number of families are closely related. One reason for this correlation is that homes are "made up of locally available materials, such as bamboo, thatch, and corrugated iron sheets and, as such, are never strong enough to hold an upper story." Quazi reports that "every new village homestead is being built on cropland." Undoubtedly there are occasional exceptions, but Quazi's point is a sound one, for Bengali villages are usually surrounded by the rice fields on which they depend.

Industrialization also consumes large areas of land. Since the mid-fifties factory construction has been one of the main causes of cropland shrinkage in western Europe and Japan. More recently, industrial development has begun to claim land in developing countries as well. Land-hungry China has been especially affected. Factories must be built in the east and south, where most Chinese live, which is also where most farmland is located. Dwight Perkins, a scholar on China, notes that the 10 percent annual industrial growth steadily consumes cropland. He believes planners are aware of this but that "there is no way around the fact that good farmland (flat, located near transport, etc.) often makes an excellent factory site."

Even more than the scarcity of fertile land, lack of water resources may constrain growth in world food output. In countries as widely separated as Mexico and Pakistan, scarcity of fresh water prevents the spread of high-yielding wheats. In the Soviet Union, water shortages are frustrating efforts to expand feed-grain production for that country's swelling livestock herds. As new irrigation options are exhausted, the link between water and bread becomes increasingly obvious.

Some 15 percent of the world's cropland is irrigated, up from 11 percent in the early sixties. Irrigation was once concentrated in the Middle East, where it first developed, but as of 1980, 46 percent of the world's irrigated lands were located in Asia.

The effectiveness of irrigation is greatly enhanced by the use of chemical fertilizer. As new areas of agricultural settlement became scarce after World War II and population growth speeded up, demand for fertilizer began to climb. In 1950 the

China: Land for the Living, Not the Dead

As the world population moves steadily toward five billion, new manifestations of population pressure are surfacing. In China, where the dead are buried under mounds that are often located on good farmland, authorities are now trying to conserve land by encouraging cremation instead of traditional interment.

A study of this burial practice in the immediate vicinity of Beijing reported that from 1949 until 1964 burial mounds claimed 526 acres of fertile cropland. Multiplied thousands of times over for the country as a whole, this loss is of great concern to Chinese political leaders. Accordingly, the government has launched a campaign to encourage cremation.

Although persuading people to change centuries-old traditions is difficult, Zhang Yizhi, an official in the ministry of civil affairs, believes that the shift to the family responsibility system will ease this transition: "If the peasants want to become more prosperous, they will not be able to let the dead occupy the limited land that is available for farming." Veneration of ancestors continues, but in this crowded country, the living compete with the dead for land.—*L.R.B.*

world used less than 14 million tons of chemical fertilizer. Within a decade that figure had doubled; in the next decade it doubled again. By 1984 world consumption of fertilizer totaled 121 million tons, a ninefold increase in thirty-four years. Eliminating its use today would probably cut world food production by at least a third. At a minimum, a billion and a half people are now fed with the additional food produced with chemical fertilizer.

Since mid-century the increase in world fertilizer use has been driven by population growth and by the expanding appetite for animal protein. As the stork outruns the plow, the role of fertilizer is magnified. The reduction in world cropland area per person since 1950 has been offset by raising per capita fertilizer use fivefold between 1950 and 1980. In simple terms, more people now means less cropland per person, requiring more fertilizer to satisfy a given dietary level.

In recent years the growth in world fertilizer use has slowed markedly. After expanding by 7.5 percent annually from 1950 through 1973, growth dropped to 5.6 percent per year during 1973 to 1979 and to 2.5 percent per year since the 1979 oil price increase. This slowdown is not due to any single influence but rather to several, many of them associated with diminishing returns and, directly or indirectly, rising oil prices.

During the last thirty years, the pattern of world food trade has been reshaped by widely varying population growth rates and levels of agricultural management among the major regions. As recently as the late thirties, Western Europe was the only grain-deficit region and Latin America was the world's leading grain supplier, exporting some 9 million tons per year. North America and Eastern Europe (including the Soviet Union) each exported 5 million tons of grain annually. Even Asia and Africa had modest exportable surpluses.

By 1950, the shift from regional grain surpluses to deficits was well under way as Eastern Europe, Latin America, Asia, and Africa all moved to the deficit side of the food ledger. With these shifts, the outlines of a new world grain-trade pattern began to emerge. North American agricultural growth gained momentum after World War II, and in 1984 United States and Canadian grain export climbed to 126 million tons. Feed grains—principally corn, sorghum, and barley—have made up an ever larger share of the total. Today, North America is not only the world's breadbasket, but its feed bag as well.

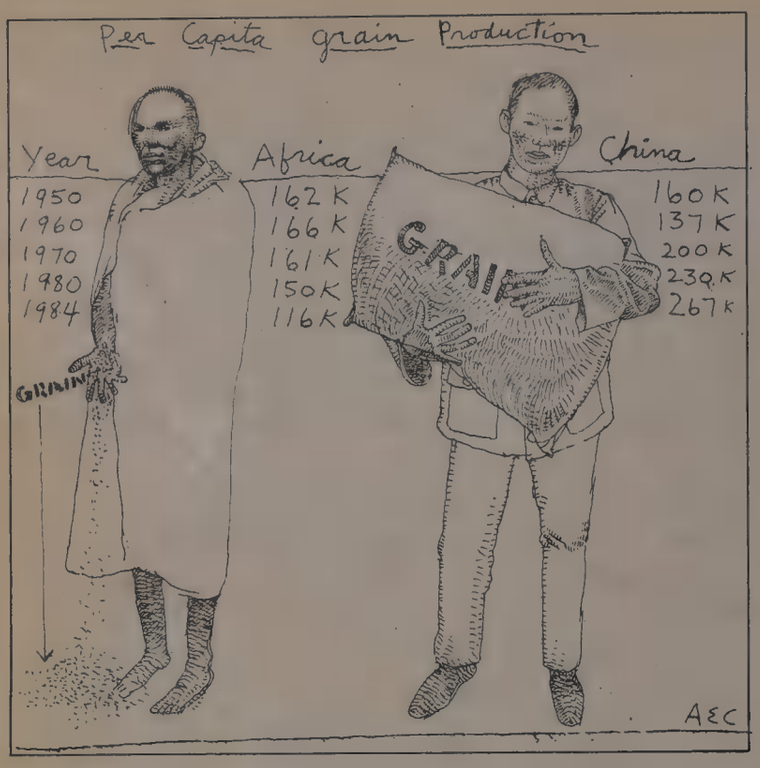
As the North American share of world grain exports has increased, it has surpassed the Middle Eastern share of oil exports and made the world more dependent on one region for its food than ever before. This overwhelming dependence on one region, and on one country in particular, brings with it an assortment of risks. To begin with, both the United States and Canada are affected by the same climatic cycles. A poor harvest in one is often associated with a poor harvest in the other. When reserves are low, even a modest fluctuation in the region's exportable grain surplus can send price tremors through the world food economy.

To restore the upward trend in per capita food production for the world as a whole, either harvests must grow or population growth must slow. Given the emerging constraints on cropland, water, and energy, it will be difficult to reestablish and maintain a 3 percent rate of growth in food production. The hope of eliminating hunger in the Third World thus rests more heavily than ever on population policies and family-planning programs.

Lester R. Brown

The world's population picture at mid-decade is one of stark contrasts.

Variations in fertility among countries have never been wider. Some populations change little from year to year or decline slightly; others are experiencing the fastest growth ever recorded. The popu-



lations of West Germany and Hungary are slowly getting smaller, for example, while those of Kenya and Syria are doubling in less than twenty years.

These disparities are placing great stress on the international economic system and on national political structures. Runaway population growth is indirectly fueling the debt crisis by increasing the need for imported food and other basic commodities. World Bank president A.W. Clausen observes that "population growth does not provide the drama of financial crisis or political upheaval but its significance for shaping the world of our children and grandchildren is at least as great."

Demographers describe the relationship between population growth and levels of development in terms of a three-staged process called "the demographic transition." In the first stage, which characterizes traditional societies, both birth and death rates are high. Societies have existed under these circumstances for thousands of years without any appreciable change in population size. Births and deaths remain largely in balance.

In the second stage of the demographic transition, living conditions get better as public health improves, vaccines become available, and food production expands. In this stage, births remain high but deaths fall. The result is the rapid population growth of close to 3 percent yearly that characterizes many Third World countries.

The third stage sees living conditions improve further, birth control become widely available and used, and births decline to again roughly offset deaths. The United Kingdom, West Germany, and Hungary are among the dozen or so countries that have completed the demographic transition, reestablishing an equilibrium between births and deaths.

Societies can remain in either the first or the final stage of the demographic transition indefinitely. This is not true, however, of the middle phase. Many developing countries have been in the middle stage since roughly mid-century. Those now in the fourth decade of 3 percent annual population growth are en route to a twentyfold expansion in a century. Unfortunately, it is difficult to imagine any country, even one that was sparsely populated at mid-century, surviving such an increase with its biological support systems and social institutions intact.

The evidence of recent years suggests that countries stuck in the second stage for more than a few decades experience mounting population pressures—pressures that eventually destroy forests, grasslands, and croplands. As these resources deteriorate, mortality rates begin to rise to reestablish a balance between births and deaths. Countries that do not make it to the demographic equilibrium of the third stage will eventually return to the demographic equilibrium of the first. Nature provides no long-term alternative.

Many of the countries that have broken out of the second stage of the demographic transition have done so with the aid of cheap energy and relatively favorable population–land ratios. Others are finding it increasingly difficult to reach the point where gains in per capita income and the use of birth control begin to reinforce each other with substantial gains in living standards.

Whether a country can move from the middle to the final stage of the demographic transition is perhaps best judged by looking at trends in per capita food production. China and Africa, with populations of just over one billion and 531 million respectively, illustrate contrasting prospects. China appears to be breaking out; Africa, having failed to do so, appears to be breaking down.

Following almost a quarter century of stagnation, per capita food production in China has climbed at an encouraging rate during the past decade. The rate of population growth has been halved since the early seventies, dropping to just over one percent per year. Grain production per capita in the mid-eighties is up by one-fourth from the early seventies. Even though China has serious environmental problems in agriculture, including soil erosion, and although its cropland base is shrinking, there is a good prospect that its living standards will continue to improve through the end of the century.

Africa, in contrast, shows no movement toward the third stage of the demographic transition. And time is running out. Population growth for the continent as a whole is close to 3 percent. The share of the population using birth control is minuscule. Grain production per capita in Africa turned downward after reaching a postwar high of nearly 400

THE WORLD OF LINDBLAD TRAVEL PRESENTS

Adventures in Luxury

You'll discover both aboard the Astor.

Here is cruising adventure in the true Lindblad tradition.

You'll cruise in Art Nouveau splendor. Aboard the Astor you enter an elegant way of life—ocean travel as it was—as it should be. The Art Nouveau mirrored walls of the main lounge reflect elegance unsurpassed anywhere at sea.

The prestigious Fielding's Worldwide Guide to Cruises awarded the Astor a four-star plus rating—and rightly so. Built in Germany in 1981, she's over 500 feet of stylish luxury with every amenity—including color TV in every cabin, and an English-speaking crew of 220 to maintain the Lindblad standard of personal service and excellence.

Luxury and Adventure Indeed.

The Atlantic Islands. Cruise from the white cliffs of Dover to the isles of the sun—the Azores, Madeira and Canary Islands. You'll sample wines from the islands, Spanish and Portuguese hospitality in Vigo and Cadiz, or Porto and Lisbon. Departing June 8, 1985.

The Fjords of Norway and North Cape. Formed by glaciers, the fjords become tunnels illuminated by the noon and midnight sun. Medieval villages combine with mountains into picture-book settings. The North Cape—where two oceans collide against cliffs a thousand feet high. Departing June 27, 1985.

Greenland and Iceland. Where Eskimo villages now dot the paths of the Norseman. Godthaab, Jakobshavn, Holsteinborg and Narssag in Greenland. Reykajvik and Vestmannaeyjar islands of Iceland. The remote islands of Faroe and the Shetlands. All are seldom visited except by polar bears, walrus, seals, raven, geese, tern and gannets. An adventure for those who want to learn, and experience the rare and unfamiliar. Departing July 22, 1985.

Antarctic Adventure. From the seldom-traveled South Atlantic to the south polar regions. Visiting the is lands of Gough, Zavadovsky, Tristan da Cunha and South Georgia, home of 28 of the 53 species of Antarctic birds. Cumberland Bay, where ancient glaciers calve into the sea. Departing November 10, 1985.

Amazon Odyssey. Rio de Janeiro, Copacabana, Ipanema, Sugarloaf, Guanabara Bay and the 120 foot statue at Corcovado. Then on to Bahia, Recife, Belem and the Amazon River stopping at Almerion, Santarem and Manaus. Upstream and downstream voyages. Departs on January 23 and February 7, 1986.

You deserve the best and with Lindblad the best is always yours.

For more information and a detailed brochure call your Travel Agent or write Lindblad Travel Inc., Dept. NH, One Sylvan Road North, P.O. Box 912, Westport, CT 06881.

pounds per year in 1967. During the mid-eighties, grain production per person is nearly one-fifth below the level of the late sixties. Several countries are reporting deaths due to starvation.

In a recent report, the World Bank expressed concern about rising death rates in several African countries. Bank officials feel that in the absence of a major initiative, a number of countries will experience a disintegration of social institutions and will revert to "bush" economies. Without a sharply expanded effort in both family planning and farming, much of the continent may drop back into the first stage of the demographic transition.

Other major areas of the world have also remained in the second stage for a dangerously long period, among them the Andean countries in Latin America (Bolivia, Chile, Ecuador, and Peru), northeastern Brazil, and the Indian subcontinent. Under the circumstances now unfolding, there is growing uncertainty about how many countries in the middle of the demographic transition will be able to break out. By the end of the century, the world may be divided into two groups: countries that have progressed into the final stage and those that have fallen back to the first stage. There are unlikely to be many countries left in the middle. The demographic transition in each nation will have been largely completed or aborted.

Countries with rapid population growth that wait too long before applying the brakes may find themselves in trouble. The first country to recognize this was China. In the late seventies, the Chinese undertook several alternative projections of population growth and resource demands. Even assuming that each couple would have just two children, the population would clearly continue to grow, because of the youthful age structure, by another 300 to 400 million people. Leaders in Beijing recognized that such an increase in population would further reduce already limited per capita supplies of cropland, fresh water, and energy, thus jeopardizing the hard-earned gains of the past generation. Rather than risk a fall in living standards, they decided to launch a one-child family program.

Like China, other Third World countries appear to be waiting too long before tackling their population problems. China is unique in terms of population size, but it shares with every country the relationship between population and local life-support systems. The principal difference between China and other rapidly growing countries such as Bangladesh, India, Ethiopia, Nigeria, and Mexico may be that the Chinese have had the foresight to make projections of their population and resources and the courage to translate the findings into policy.

In one Third World country after another, the

High- and Low-tech Birth Control

The world faces two family planning gaps: one between the demand for contraceptives and their availability, and another between societies' need to reduce population growth quickly and couples' willingness to cooperate. Efforts to close the first gap have led to a wide array of contraceptive practices.

Worldwide, sterilization protects more couples from unwanted pregnancy than any other practice, largely because of its prevalence in three populous countries—China, India, and the United States. Oral contraceptives (the pill) rank second, partly because they are extensively used in both industrial and developing countries.

Patterns of contraceptive use vary widely among countries and do not necessarily correspond to levels of development. The pill, for example, completely dominates Egypt's family planning program: Seventeen of every twenty couples using contraception rely on this method. And in Indonesia nearly three out of five couples practicing contraception take the pill.

Ironically, this modern contraceptive is prevalent in some key developing countries at the same time that traditional techniques are still extensively used in some industrial nations. In France, for example, fully a third of the couples practicing contraception still use traditional methods, such as withdrawal. In Eastern Europe, these older techniques also dominate the effort to limit family size because modern contraceptives are not consistently available; as a result, the number of abortions in these countries sometimes exceeds the number of live births.

India is unique in its overwhelming dependence on sterilization, both male and female, largely because of vigorous government promotion and the failure, until recently, to provide other methods, such as oral contraceptives. Reportedly, five of every six couples protected by contraception rely on sterilization, with most of the remainder relying on the condom and IUD.

Women in China, in contrast, depend heavily on the IUD—half the 118 million married women of reproductive age who are using contraception choose this method. Sterilization is the second most popular method in China, with the pill a distant third.

In the United States, sterilization has overtaken the pill as the most widely used contraceptive method, chosen by one-quarter of the couples who practice birth control. The pill accounts for more than one-fifth. Most of the remaining couples choose diaphragms or IUDs. The pattern in the United Kingdom is strikingly similar, largely because of cultural similarities.

Cultural influences shape contraceptive use in unexpected ways. In Indonesia, for instance, the IUD is popular on Bali, which is populated by Hindus. But on Java, with its predominantly Muslim population, it is far less prevalent. Apparently Balinese women are accustomed to male childbirth attendants, whereas Javanese women rely on midwives and are thus reluctant to have a doctor, usually a man, insert an IUD.

The availability of contraceptives alone will do nothing to narrow the troubling gap between the family size desired by couples in some regions and the number of children their societies can support. In Africa, where living standards are already falling, failure to encourage smaller families will surely cancel the gains won by providing contraception.—*L.R.B.*

pressure on local life-support systems is becoming intolerable, as can be seen in their dwindling forests, eroding soils, and falling water tables. If other governments take a serious look at future population–resource balances, they may reach the same conclusion the Chinese did. And they may be forced to choose between a one-child family program and falling living standards. Given the unprecedented numbers of young people who will reach reproductive age within the next two decades, a generation of one-child families may be the key to restoring a sustained improvement in living standards. Success in striving for an average of one child per family will bring its own problems, including a severe distortion of age-group distribution, but it may be the price many societies must pay for neglecting population policy for too long.

Lester R. Brown

Opportunities to save energy are many and impressive. A single

decision in the United States—to raise automobile fuel economy to forty miles per gallon—or in the Soviet Union—to produce steel as efficiently as Japan does—would save as much energy as Brazil now consumes. Such opportunities can be found again and again in each of the consuming sectors.

But are such decisions in the offing? A survey of forecasters shows a consensus that by the year 2025 worldwide commercial energy demand will increase from about 135 million barrels of oil equivalent per day to 300 million barrels per day. If this scenario were to unfold, the oil output of two new Saudi Arabias would be needed. In addition, the coal production of the world would more than triple. Four and one-half as many rivers would have to be impounded behind hydroelectric dams. A total of 365 large nuclear power plants would be added.

Among the consequences of using so much energy would be greater risk of acid rain, changes in climate induced by carbon dioxide, species extinctions, water degradation, and proliferation of nuclear weapons. According to the forecast, acid-rain-causing sulfur emissions would triple in forty years. And in the next century, the atmospheric concentration of carbon dioxide (compared to preindustrial levels) would double and cause an atmospheric temperature increase large enough to flood coastal cities and shift rainfall patterns all over the globe.

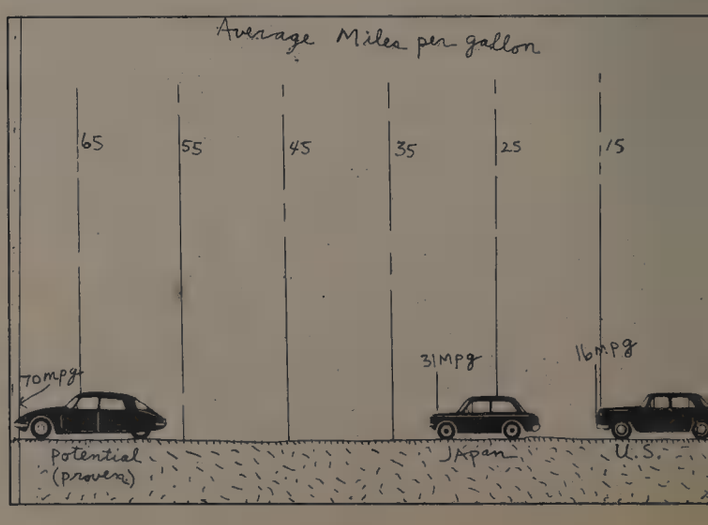
The economic prospect of a future with high energy demands is similarly unappealing. Much of the Third World's debt has been incurred to finance energy imports. Foreign payments for oil consume the largest share of total export earnings for many countries, including half of those of Japan and Brazil. Expensive hydroelectric and nuclear energy systems have added to this reservoir of debt.

Industrial processes consume more of the world's commercial energy than either transportation or housing. Industry, at the same time, has provided the largest efficiency gains of any energy-using sector since World War II, with an annual rate of improvement of more than one percent even as energy prices declined. This rate tripled in Western nations after the energy price increases of the seventies. Despite the gains, however, there is still an enormous potential for cutting energy costs in existing plants, and builders of new production facilities can choose far more efficient equipment and processes.

Japan's steel industry, for example, is a leader in efficiency. The Japanese use 30 percent less energy per ton than the world average, and only half as much as the Chinese and Indians. The Soviet Union, the world's largest steel maker, uses 65 percent more energy per ton than Japan. The Japanese reduced energy use by retrofitting mills that produce iron from ore. But even the Japanese steel industry could be 20 percent more energy efficient, especially if it relied more on recycling, which saves up to two-thirds of the energy used to produce steel from ore.

Some measures, such as improving electric motors, are available in industries as diverse as paper, chemicals, and cement making. Electric motors consume more than 80 percent of all electric energy used in U.S. industry and a remarkable 40 percent of all electricity used in Brazil. If Brazil invested in more efficient motors and motor speed controls, it could save 10,000 megawatts by the year 2000, or more than 17 percent of its projected new demand for generating capacity.

The macroeconomic models in vogue today implicitly assume that conservation will not work well. Most assume that the United States, for example, will not reach the current Japanese level of effi-



Six Ounces of Gasoline in a Soda Can

Throwing away an aluminum beverage container wastes as much energy as filling the same can half full of gasoline and pouring it out on the ground. Failing to recycle a daily edition of the *New York Times* or the *Washington Post* wastes just as much. Recycling, fortunately, yields back much of the energy invested in materials. It saves 90 percent of the energy required to make aluminum from bauxite, more than half that needed to make steel from iron ore, and a third of the energy needed to make paper from wood.

Because the production and consumption of energy in wood, aluminum, and steel processing create severe environmental problems, recycling also protects the environment. It reduces air pollution, strip mining of the coal used by power plants, oil spills, and solid waste. Yet despite recycling's advantages, the world has fallen far short of achieving its potential. Only about one-fourth of the paper, aluminum, iron, and steel used in the world is recovered. This rate could be doubled or tripled for each material.

Japan, the Netherlands, and South Korea lead in waste paper recovery and use. Japan collects almost half of the paper it consumes. The Netherlands collects about 45 percent. South Korea makes 40 percent of its paper from waste paper imported mainly from the United States, which collects only a quarter of the large amount of paper it uses.

In 1970 the United States ranked last in aluminum recycling. But producing aluminum from ore is very energy intensive, and the energy price increases of the seventies provided a powerful incentive to recycle. As a result, the rate of recycling aluminum beverage containers, for example, has increased from 15 to more than 50 percent. One innovation that helped bring this improvement is the "reverse vending machine." The machine accepts aluminum cans, rejects ferrous cans, glass, or other unwanted objects, weighs the aluminum deposited, and dispenses money or coupons in payment.

The nine states that now have mandatory beverage container deposit laws, however, recycle about 90 percent of their beverage containers. Still, each year the United States throws away more aluminum in beverage containers than is made on the entire continent of Africa.

In Japan and the Netherlands, recycling of metals, paper, and glass works well because consumers sort their waste into separate containers for collection. Mandatory source separation has worked well in Islip, New York, where 50 percent of the population has complied willingly. New laws in Minnesota, Oregon, Michigan, and in Canada are now giving citizens the opportunity to recycle.

Many people still lack basic material amenities—metal for water pipes, wood for housing—and the world population is still growing. Thus, to improve or even maintain living standards will require much higher energy efficiency in materials production if unacceptable economic as well as environmental costs are to be avoided. As Jean-Jacques Rousseau wrote in 1754, "It is obviously contrary to the law of nature . . . for a handful of people to wallow in luxury while the starving multitude lacks the necessities of life." Recycling can help provide necessities.—*W.U.C.*

ciency in steel for thirty-five years. They assume that the Soviet Union, China, and India will not match today's performance by the Japanese until after the year 2050.

Although the transportation sector uses less energy than industry, it uses oil almost exclusively. Automobile fuel economy, mass transit, and efficient freight hauling thus offer the largest oil savings. Private cars consume about 17 percent of the oil used each year. The United States, for example, uses 10 percent of the world's oil output as gasoline for motorcars and light trucks.

The world average auto fuel economy is about twenty-one miles per gallon, while Japan has a level of thirty-one and the United States only about sixteen. If by 2000, American cars—the world's least efficient fleet—were as efficient as the Japanese cars, world oil use would be 5 percent less than today. Doubling auto fuel efficiency worldwide would allow savings of about 8 percent of world oil output. Achieving this should cost less than $20 per barrel saved. The alternative, producing gasoline or alcohol fuel, will cost $40 to $60 per barrel.

There are many ways to achieve high fuel economy levels. Reducing auto weight, for example, can save 25 percent of the energy used in the typical American car. Designing more efficient engines can yield another 20 percent improvement. Installation of efficient, continuously variable transmissions can save 20 percent. Simply installing the most efficient tire available on the market today would improve the fuel economy of most cars by one to three miles per gallon. Several automakers have produced prototype cars that travel seventy to ninety miles per gallon.

Mass transit is inherently more efficient than the private car. In West Germany, for example, railroads use only one-fourth as much energy as cars to move people an equal distance. The autobus is comparable in efficiency. No mode of passenger transportation, however, is both more flexible and more efficient than the van pool. Jitneys—vans or other small vehicles operated like taxis along fixed routes—provide efficient, inexpensive mass transit in more than a dozen cities in developing countries around the world.

In industrial nations, energy use in buildings can be cut in half. Appliances for space heating, water heating, air conditioning, and refrigeration require three-fourths of the energy used in U.S. buildings, with 42 percent going for space heat alone. Typical gas furnaces are about 70 percent efficient, but new gas-fired systems are up to 94 percent efficient. Unfortunately, consumers usually choose the less efficient units. Furnace size and fuel use can be reduced with more insulation, and Swedish homes, on average, have twice the insulation values of homes in Minnesota.

Japanese refrigerators, even adjusted for smaller size, are twice as efficient as U.S. refrigerators. They do not sacrifice frost-free features or other conveniences to attain efficiency.

Half the electricity used in the United States for lighting could be saved by substituting more efficient bulbs and fixtures. This savings would total 420 billion kilowatt-hours per year—40 percent more electricity than the entire annual hydroelectric or nuclear power output of the United States.

Household energy use in the developing world—mainly firewood for cooking—is also very inefficient. The widening circle of firewood collection, moreover, adds to the deforestation and soil erosion caused principally by lumbering, agriculture, and drought. More efficient stoves would cut fuelwood use by 25 to 50 percent. The key to saving firewood and dung is the dissemination of low-cost, prefabricated stoves that are both durable and simple to use and service.

By making use of the available conservation technology, energy growth can be cut in half by the year 2025. Oil production equal to the current output of Saudi Arabia and Venezuela would be saved. Coal amounting to 40 percent more than the entire world uses today would be saved. The net economic savings in energy use would total more than $1 trillion per year in 2025.

Acid-rain-forming sulfur emissions, instead of tripling, would only increase about one-third. Emission-control technologies would still be required, but their cost would be drastically reduced. Conservation would also reduce carbon dioxide emissions sufficiently to provide time to find substitutes for fossil fuels.

To achieve these savings, by the year 2000 the world average energy efficiency in steel making, for example, will have to be equal to that of the Japanese today, and equal to the best currently available technology by 2025. Similar targets must be met for aluminum, paper, cement, and chemicals manufacture. Automobiles would have to average thirty-one miles per gallon by the end of the century and forty-five miles per gallon by 2025. Efficiency gains would permit the same amount of residential energy used today to provide twice as much space heat, hot water, air conditioning, and refrigeration worldwide by 2025.

All governments must take major policy initiatives to achieve this conservation potential. The crucial policies include market pricing of energy, elimination of subsidies for energy use, implementation of regulations that overcome market failures, provision of consumer information, research and development, and visible encouragement of conservation by leaders at all levels.

The most efficient nations are those that not only have accepted the reality of market prices but also bill energy consumers for the environmental and social costs of energy. The tax on gasoline exceeds the price, for example, in Argentina, Belgium, Colombia, the Netherlands, South Korea, and the United Kingdom. In South Korea, the tax exceeds $2 per gallon.

Market pricing, even coupled with energy taxes, will not entirely solve the problem. The classic example of how markets sometimes fail is the appliance bought by a landlord who does not pay the energy bill for operating it. The landlord has every incentive to buy the least costly furnace or water heater, not to pay more for one that will save energy costs. The tenant who will pay the energy bill has no say in the choice of appliance. The obvious targets for minimum performance standards are automobiles, furnaces, water heaters, air conditioners, refrigerators, and heat pumps.

Policy makers are thus presented with the task of making energy policy on numerous fronts. Unless falling oil prices are stabilized, the current situation could start a new cycle of energy consumption growth and rapid price increases.

William U. Chandler

Replacing fossil fuels with renewable energy that is environmentall

benign is one of the keys to creating a sustainable society. From the time the first coal mines were opened and the first oil wells were drilled, the world has been slowly but inexorably running out of fossil fuels. For more than a decade, scientists and entrepreneurs worldwide have been working to improve renewable energy technologies and bring them into widespread use. Much of the progress in the past decade was stimulated by government-sponsored research and development. Although modest compared with government support of the nuclear industry, the achievements are impressive and helped pave the way for future progress.

The challenge in the years ahead is to maintain the momentum despite falling oil prices, which threaten to lure policy makers back to the sort of complacency that helped produce the energy crises of the seventies. Amid falling oil prices and laissez-faire government energy policies in some countries, renewable energy development might be expected to lag badly. Instead, worldwide reliance on renewable energy sources has grown more than 10 percent per year since the late seventies.

Today, renewable energy sources provide approximately 18 percent of the world's energy,

The 1985 Turbo New Yorker. Once you drive it, you'll never go back to a V-8 again.

Chrysler introduces the new technology of driving: Turbopower* in its most advanced luxury sedan.

Here is the confidence of front-wheel drive, the security of advanced electronics and the quiet, smooth ride you expect in a fine luxury car.

And here are the luxuries you demand. Automatic transmission, power windows, power steering, power brakes, power remote mirrors and individual pillow-style reclining seats are all standard.

And finally, here is the new technology of turbo-power. More power to move you. To accelerate. To pass. To cruise in serene comfort...yet with remarkable fuel efficiency. 23 hwy. est. mpg 20 city est. mpg.**

Turbo New Yorker merits careful consideration by every luxury car owner. It is backed by a 5-year/50,000-mile Protection Plan covering drivetrain, turbo and outer body rust-through.†

The new technology of driving must be experienced. So Chrysler invites you: test drive Turbo New Yorker. Once you drive it, you'll never go back to a V-8 again.

Purchase or lease your 1985 Turbo New Yorker at your Chrysler-Plymouth dealer.

And buckle up for safety.

Chrysler. The best built, best backed American cars.††

Best backed based on warranty comparison of competitive vehicles.

Northwest Orient's Alaska: Nonstop or direct every day from every corner of the U.S.A.

Going to Alaska this summer? Beginning June 6, Northwest Orient will make the going easier . . . with more nonstops and more direct flights from more of America.

■ Daily nonstops from Minneapolis/St. Paul and Seattle/Tacoma.

■ Daily direct flights from the West Coast (Los Angeles, San Diego and Portland); from the Midwest (Chicago); from the Northeast (New York City and Boston); and the Southeast (Tampa/St. Petersburg and Miami).

■ Plus convenient connecting service from other cities coast to coast and border to border.

If you're planning an Alaska trip before June 6, you'll find our spring schedule (4/28 to 6/6) very accommodating too.

Enroute, you'll enjoy meals with the hearty flavor of Alaska—such as Alaskan salmon, reindeer sausage or crab omelets. There's complimentary Yukon Jack for Klondike Coffee and Midnight Sunrises.

For information and reservations, call your travel agent.

Or call Northwest Orient toll-free at (800) 225-2525.

NORTHWEST ORIENT

The world is going our way.

mainly in the form of hydropower and wood fuel. That figure has risen only slightly since 1973, but more rapid growth is likely in the years ahead. The list of important renewable energy sources will grow to a half dozen or more and will include wind power, solar heat, geothermal energy, waste products, alcohol fuels, and photovoltaic cells. Although none of these will solve the world's energy problems by themselves, collectively they can meet the modest additional energy needs of a more energy efficient world economy.

Wood fuel is the world's most heavily used renewable energy source, and the examples of India and the United States highlight a striking dichotomy. Both now burn approximately equal amounts of fuelwood, but in the United States the 130 million tons of fuelwood used annually represents only 4 percent of energy use, whereas in India it supplies one-fourth the country's energy. Overused in the developing world, fuelwood is a necessity that is in ever shorter supply. Largely supplanted by other energy sources a century ago, wood is now underused in the industrial world.

More than 100 million people in the Third World cannot get enough wood to cook their food, and more than a billion are meeting fuel needs only by overcutting and depleting their wood resources. Much of Africa faces a daunting energy crisis as well as a food crisis. Many forests have been destroyed and others dwindle yearly under the pressure of growing populations. Efforts to accelerate the planting of forests, introduce more efficient cookstoves, and find alternative fuels have been under way for almost a decade but show limited success so far.

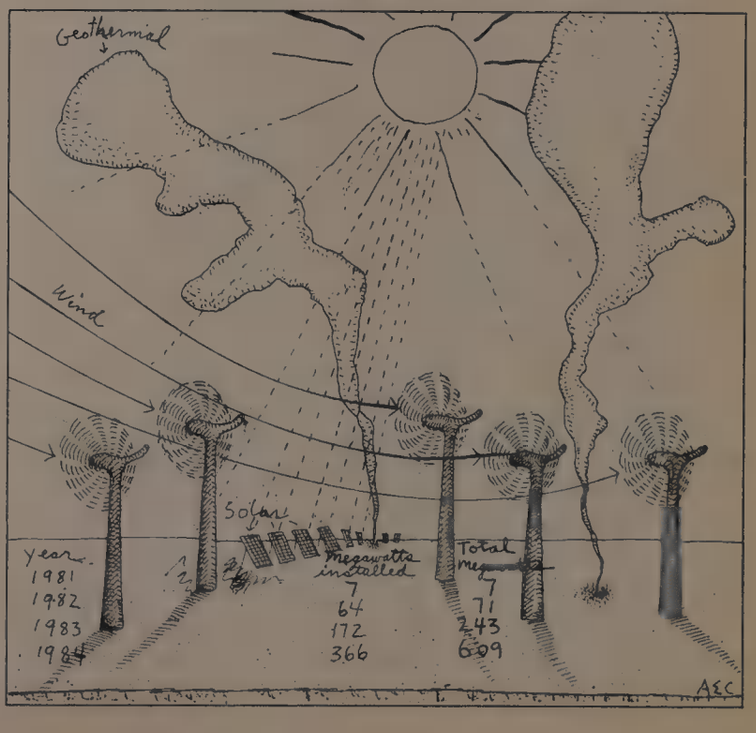
Leading the industrial world's return to wood fuel is Sweden, which plans to burn fifteen times more fuelwood, wood chips, and forest residues by the year 2000, enough to supply 12 percent of the country's energy. Wood will be used to run factories, to provide district heat to small towns, and to produce methanol for automobiles. In the United States, wood energy use has increased by more than 50 percent since 1973, thanks to homeowners who installed wood stoves to reduce their soaring heating bills. In 1981 alone, two million wood stoves were purchased, and American homes collectively burned 48 million tons of wood—equal in heating value to 100 million barrels of oil. In rural areas of New England and the West, wood is now the main heating fuel.

Lately, wood burning by U.S. industry and utilities has also been increasing. They now use nearly twice as much wood energy as households do. The forest products industry now derives 60 percent of its energy from wood, and other industries are also beginning to install boilers that can run on wood pellets, chips, bark, or pulp. Procter and Gamble spent $30 million to convert its large Staten Island, New York, plant from oil to wood in 1983. In Vermont, the Burlington Electric Company completed a 62-megawatt, $76 million wood-fired power plant, the world's largest, in 1984. There are an estimated twenty-six wood-fired power plants planned or under construction nationwide.

Hydropower is the second largest renewable energy source, providing one-quarter of the world's electricity. Although hydropower is usually considered a fully developed energy source, a hydropower construction boom is under way in many countries, particularly in the Third World. During the past five years, ten countries have increased their capacity by more than 57,000 megawatts—the equivalent of fifty-seven large nuclear reactors. Despite debt burdens that have slowed some projects, the World Bank expects hydro capacity to double in the eighties. In China alone, the 10,000 megawatts of hydro capacity under construction in the early eighties will expand the country's hydroelectric output by more than half.

Although justified on strict economic grounds, many large hydro projects cause social and ecological problems. Too often, dams have been constructed without sufficient planning. Inadequate fish-handling facilities have eliminated access to essential spawning areas, reservoirs have expanded the breeding grounds for snails that spread schistosomiasis, and valuable farmland and wilderness areas have been inundated. Indigenous peoples are sometimes forced off their homelands, and their cultures are irretrievably lost. Large hydro projects must be considered carefully before they are undertaken, and some should be foregone entirely.

Wood and hydropower already contribute substantially to the global energy budget, but other renewable energy sources that make only a minor contribution today hold enormous promise for the



There's an Awful Lot of Alcohol in Brazil

No country has put more effort into developing renewable sources of energy than Brazil. With the world's tenth largest economy, a pauper's endowment of fossil fuels, and a foreign debt of $95 billion, Brazil desperately needs to develop indigenous and sustainable energy supplies. In the aftermath of the 1973 energy crisis, Brazil's leaders developed plans to expand hydropower, alcohol fuels, and wood energy, all on a massive scale. Never before has a country developed such a diverse renewable energy program or made renewables such a key part of its development plans.

Brazil is investing tens of billions of dollars in large hydro projects that will provide electricity for cities and industries. Its hydro capacity is scheduled to double by 1993, which could make Brazil second only to the United States in hydroelectric capacity. Symbolic of Brazil's approach to hydropower is the Itaipu project, with a dam five miles long and half the height of the Empire State Building. Estimated to cost $18 billion, Itaipu will be the world's largest hydro project and provide enough power for five million people.

More unusual is Brazil's alcohol fuels program. Launched in the early seventies, the multibillion-dollar Proalcool program provides incentives for turning the country's abundant sugar cane crop into alcohol that can be burned in modified internal combustion engines. Brazil now has 1.2 million automobiles that run on straight alcohol, and another 9 million run on a 2 percent alcohol-gasoline mixture. Overall, alcohol meets 4 percent of the country's automotive fuel needs. Brazil plans t triple production of alcohol fuel by 1993, which, combine with successes in oil exploration, may allow it to reach its go of not having to import oil for cars by the early nineties.

Brazil is working to harness other renewable energy source as well. Scientists are investigating a number of vegetable oi that may one day substitute for diesel fuel in the country's mi lions of trucks. In addition, wood energy has an enormous p tential to provide heat and power for industry. A major pr gram has been developed to shift the steel industry fro metallurgical coal to wood-derived charcoal.

Brazil's renewable energy programs are certainly the mo ambitious and in many ways the most successful. But they a not without problems. Large hydro projects have inundate wilderness areas and displaced native peoples. Alcohol fu production has supplanted some food production and threa ens to exacerbate the country's unequal distribution of incom And Brazil has put surprisingly little effort into improving e ergy efficiency, which could further reduce oil dependence at small cost. Brazil stands as an important example of the ro that renewable energy sources can play in developing countri and of potential problems that must be considered.—*C.P.*

future. One example is solar heating and cooling, a technology that is being developed by private companies in dozens of nations. The big success stories are Japan, which has 4 million solar hot-water systems in place, and Israel, where about half the homes heat their water with solar energy. The United States has the world's largest collector industry and about a million solar buildings in place. But the complexity of the systems must be reduced and their cost lowered to realize their potential.

Geothermal heat is the only renewable energy source that does not depend on sunlight. Iceland's capital city of Reykjavik is almost entirely heated by geothermal steam. Another major geothermal resource is the Geysers (in California), whose steam supplies 1,300 megawatts of electricity, as much as the world's largest nuclear plant. Efforts to harness geothermal resources are under way throughout the Pacific Rim countries. In the Philippines, geothermal capacity is scheduled to double, and lead the world, by the end of 1985. Worldwide geothermal generating capacity rose 20 percent in 1984.

The fastest-growing renewable energy source is wind power, thanks to the new business of "wind farming" begun in California. Since 1981, more than 8,000 turbines have been erected in the state's mountain passes, mostly in Altamont, Tehachapi, and San Gorgonio, where winds blow at an average speed of fifteen to twenty miles per hour. Together, these machines produce enough electricity for 200,000 California households, and their presence provides a powerful visual symbol of California's leadership in the development of renewable energy.

California has some of the country's most concentrated wind resources, and the wind farm boom was spurred largely by small entrepreneurs. Thanks to requirements by California regulators that utilities buy privately produced power at a competitive price, developers are able to raise the capital needed for wind farm development. Funding often comes from limited partnerships in which investors contribute capital in return for tax credits and a share of the electricity revenues. The state also has a 25 percent wind investment tax credit to go with the 15 percent federal credit. In 1984, more than $500 million was invested in 55 California wind farms.

The quality of the wind farm projects varies widely. Although prominent breakdowns have generated negative publicity for wind farms, the performance and reliability of most projects are steadily improving. The average cost of wind turbines has fallen by 50 percent to approximately $1,700 per kilowatt. Calculations based on these figures indicate that the cost of wind power—without tax credits—is less than the cost of power from new nuclear plants. With mass production of somewhat larger machines, wind power will become an economical energy source in many parts of the world.

Wind farming is starting to catch on outside California. Wind farms have been installed in a half dozen U.S. states, and efforts to develop wind power are under way in Europe, particularly in Denmark, Great Britain, the Netherlands, Sweden,

and West Germany. European turbines have turned out to be extremely reliable and are being modified and brought into large-scale production to serve the California market. Many developing countries also have substantial wind power potential, and efforts are being made to identify good sites. North Africa and the Caribbean islands are particularly promising areas for wind farms.

If there is one lesson to be learned from a decade of renewable energy development, it is that efforts to make long-range forecasts about such rapidly evolving technologies are pointless. But there can be little doubt that the dozen or so renewable energy sources, together with improved energy efficiency, can form the foundation of a more sustainable and less environmentally disruptive energy system of the future. Intelligent and sustained government support is one of the keys to realizing this potential.

Christopher Flavin and Cynthia Pollock

Building a sustainable society is possible. But it is not easy.

Population policies and national priorities on resource use will have to be thoroughly overhauled. The cornerstone of such a reorientation is the realization that our security and future well-being may be threatened less by the conflicts among nations than they are by the deteriorating relationship between ourselves, soon to be five billion, and the natural systems and resources that sustain us.

The principal elements of an effort to build a sustainable society are straightforward. They include economic and population policies that respect the carrying capacity of local ecosystems, protect soils, and preserve the diversity of landscapes and species. Any strategy that aims to improve living standards will recognize the depletable nature of fossil fuels. Successful economic plans will capitalize on the abundance of labor and minimize the use of scarce capital.

The ecological indicators of today foreshadow the economic trends of tomorrow. If we are interested in food prices at the end of the century, we should be looking at soil erosion today. For some idea of the cost of lumber and the price of housing a generation hence, we should be following deforestation trends today. If we want to know what types of seafood we will be eating a decade from now, we should be analyzing the areas of overfishing today.

Add the interaction of these trends across international boundaries, and the complex analytical task becomes evident. In effect, the emergence of a highly developed international economy provides a way of transmitting scarcities from one country to another, a domino theory of ecological stress and collapse. In times past, civilizations whose food systems were undermined by erosion declined in isolation. But in the integrated global economy of the late twentieth century, food—like oil—is a global commodity. A country that loses too much topsoil needs to import more food, thereby raising the pressure on soils elsewhere.

Countries that address these challenges face difficult choices. In China, authorities encourage cremation rather than traditional burial to conserve cropland. West Germans may now have to choose between reducing automobile use and sacrificing their forests. For many Third World countries, the choice is between an abrupt lowering of birthrates or a certain decline in living standards.

Trade-offs between food and energy are particularly difficult. In Brazil, a massive government program to become self-sufficient in liquid fuels by producing alcohol from sugar cane has reduced the outlay of scarce foreign exchange for oil, but it has also increased the pressures on soil and displaced small farmers from their land.

Difficult as these choices seem, they pale beside the costs of inaction. India has long advocated family planning, and its population is expected to reach replacement-level fertility by 2010. Yet this slow but steady braking of demographic momentum will keep India's population growing until it reaches 1.7 billion. In effect, India would add the equivalent of China's population to its current numbers. For a country that is now losing some 6 billion tons of topsoil from its cropland each year, the prospect of having to feed another billion people is frightening.

Nigeria faces an equally daunting prospect. If birthrates fall to the level needed to just replace parents by 2035, Nigeria's youthful population will reach 618 million, more than now live in all of Africa. This extraordinary population growth is already being supported with imported food paid for by oil exports, and the oil will be largely depleted by 2000.

Mexico may have also waited too long. Its current population of 73 million is projected to reach 199 million before growth comes to a halt. Water is already critically short, not only in Mexico City but in the central and northern sections of the country as well. With a near tripling of Mexicans in prospect, stringent water rationing seems inevitable.

These population estimates for key Third World countries are official World Bank projections, but there is an air of unreality about them. Although sound in narrow demographic terms, they bear little relation to the deterioration of basic life-support

systems and to the resultant hunger and deprivation. The main question facing political leaders in these countries is whether this unsupportable population growth will be checked by vigorous family planning programs or by starvation.

Although restoring improvements in living standards is a formidable task, all the ways of doing so reinforce one another. For example, planting trees conserves soil and water, slows the buildup of carbon dioxide (CO_2), stabilizes the hydrological cycle, minimizes flooding and drought, provides employment, and creates a renewable source of energy. Similarly, slowing population growth makes virtually all problems much more manageable, as those countries that have reduced fertility are discovering. Increasing energy efficiency cuts down on CO_2 buildup, reduces acid rain and hence protects forests, and provides higher living standards with a given supply of energy. Recycling materials also illustrates this pattern of reinforcement: As recycling increases, energy requirements dwindle, air pollution and acid rain decline, pressure on forests is reduced, and employment increases.

Our effects on natural systems, whether constructive or destructive, will change relationships not only among countries but also between generations. Fossil fuel combustion today promises to alter the climate of tomorrow. Our destruction of plant and animal species impoverishes the world of our children and grandchildren. At issue is whether we can act on behalf of future generations by having fewer children and by shifting to sustainable technologies and consumption patterns.

Chandler, Christopher Flavin, Cynthia Pollock, Sandra Postel,** and **Edward C. Wolf,** he authored *State of the World 1985: A Worldwatch Institute Report on Progress Toward a Sustainable Society,* edited by Linda Starke and published by W.W. Norton and Company, New York and London, 1985. Most of the material in this supplement was drawn from this extensive work.

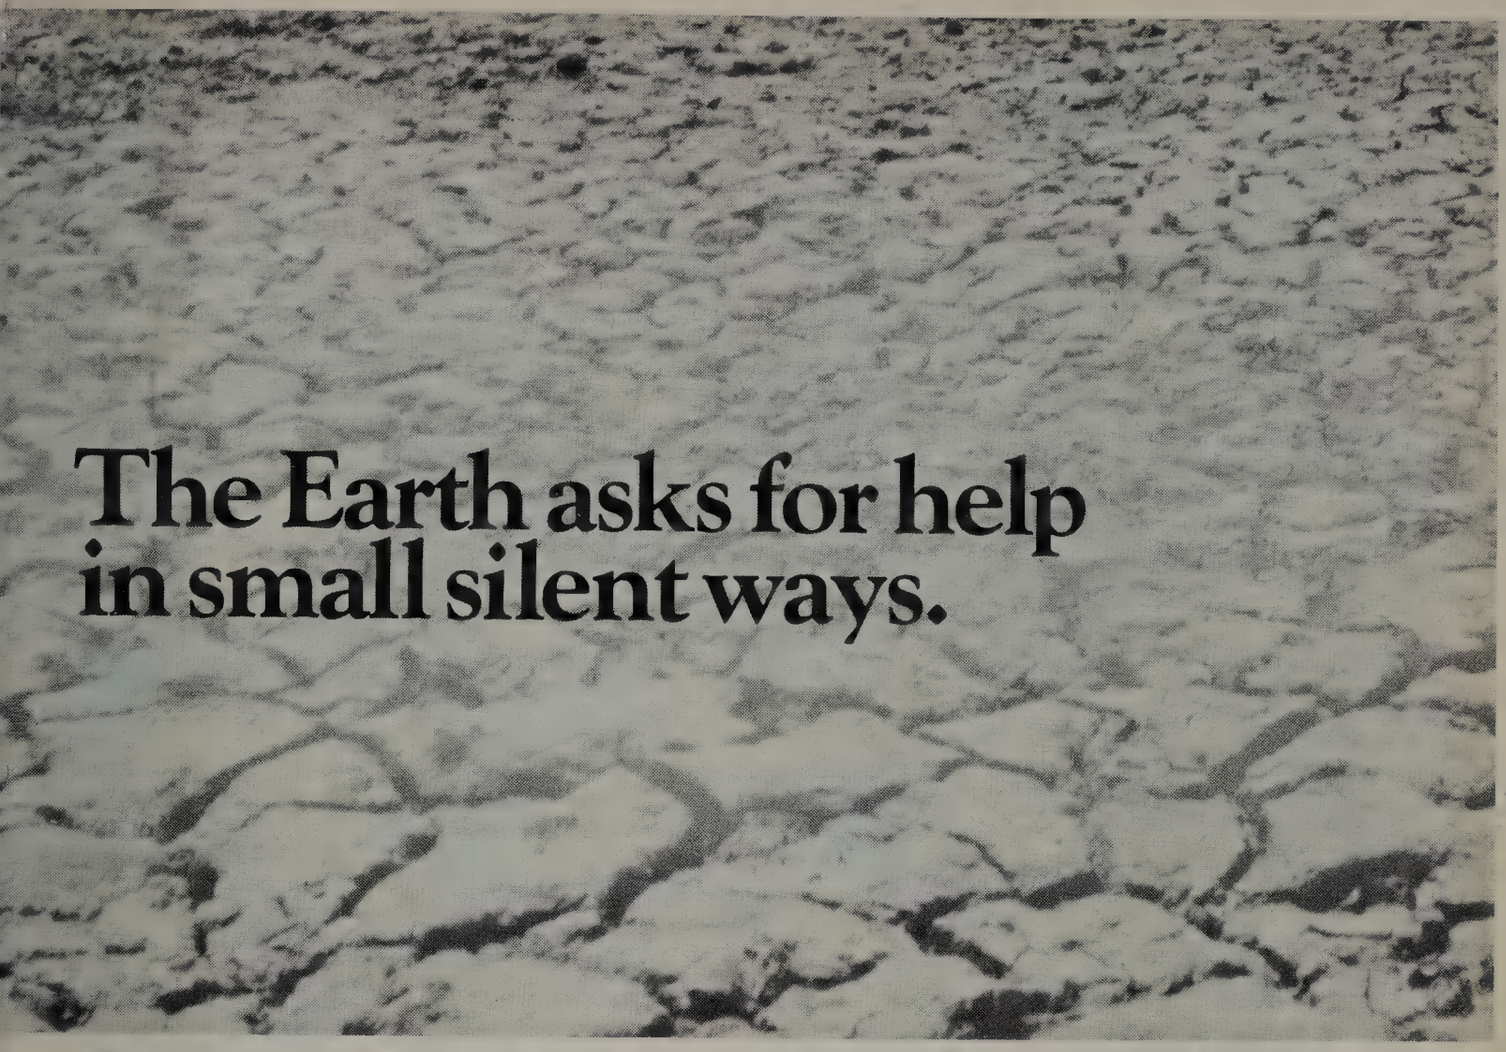
Daniel Deudney and Christopher Flavin's *Renewable Energy: The Power to Choose* (New York: W.W. Norton and Co., 1983) describes public policies that promote the development of renewable energy sources and reviews the steps being taken to harness various alternative energy technologies. *Energy: The Conservation Revolution*, by John H. Gibbons and William U. Chandler (New York: Plenum Press, 1981), focuses on U.S. energy policies, reviewing energy demand projections and technical potentials for savings in industry, transportation, and buildings. Howard S. Geller's *Energy Efficient Appliances* (Washington, D.C.: American Council for an Energy-Efficient Economy, published June 1983) explains the performance and economics of efficient home appliances and discusses policies to promote their use. The council also periodically publishes a list of the most energy efficient appliances on the market. Both are available from the ACEEE, Suite 535, 1001 Connecticut Avenue NW, Washington, D.C. 20036. *Energy Efficiency in the Steel Industry With Emphasis on the Developing Countries* (Washington, D.C.: World Bank, 1984) looks at energy costs and consumption in steel making, providing an economic and technical analysis of opportunities for conservation in this field. It is available for $5 from the World Bank Publications Department, P.O. Box 37525, Washington, D.C. 20013.

The Crowded Earth (New York: W.W. Norton and Co., 1984), by Pranay Gupte, a former foreign correspondent for the *New York Times*, is a popular introduction to population problems and the related issues of health care, aging, migration, and urbanization. The World Bank's *World Developme Report 1984* (New York: Oxford University Press) focuses c population and demography in the Third World, analyzir population trends and their impacts on people's welfare ar outlining requirements for sustaining recovery from the rece worldwide recession. It is also available from the bank's pub cations department ($8).

In *The Primary Source* (New York: W.W. Norton and Co 1984), Norman Myers explores the ecological and econom roles of tropical forests, covering their biological richness ar implications for species diversity as well as the pressures the are undergoing from commercial timber and subsistence agr culture. *Water for Western Agriculture*, by Kenneth D. Fre erick and James C. Hanson (Washington, D.C.: Resources f the Future, 1982), surveys the role of irrigation in the agricu ture of the Western states, focusing on its past importance ar future prospects in view of such factors as mining of groundw ter, increasing energy prices, and environmental problems. paperback edition ($15) can be obtained from The Johns Ho kins University Press, Customer Service, P.O. Box 485 Hampden Station, Baltimore, MD 21211.

Stephen Schneider and Randi Londer's *The Coevolution Climate and Life* (San Francisco: Sierra Club Books, 1984) i troduces the history, dynamics, and implications for human s ciety of climate changes. William W. Kellogg and Robe Schware's "Society, Science and Climate Change" (*Forei Affairs,* Summer 1982) investigates the modifications in pu lic policy that may be required to cope with rising levels of ca bon dioxide in the atmosphere. In *Acid Rain in Europe a North America: National Responses to an Internation Problem* (Washington, D.C.: Environmental Law Institu 1983), Gregory S. Wetstone and Armin Rosencranz, both a torneys, investigate the national policies and strategies of t United States, Germany, Norway, Sweden, Canada, t United Kingdom, and Japan to control this form of pollutio For a copy, send $14 to the Environmental Law Institu Publications Department, 1346 Connecticut Avenue N Washington, D.C. 20036.

Rita Camp



The Earth asks for help in small silent ways.

Please help before it's too late.

You're looking at what used to be a tropical rain forest.
But poverty-stricken people, desperate for firewood to cook their meager meals, have turned woodlands into wastelands by clearing acres and acres of trees. Sadly, by doing so they jeopardize not only their own existence, but our very Earth.

Trees mean life.
Every two minutes, our world loses approximately 35 acres of trees.

Without trees, heavy rains wash away the Earth's topsoil. Without trees, turbulent winds and extreme temperature turn it into a hostile desert which can't absorb water...can't support vegetation for livestock...can't produce crops for man.

It's a grievous, ever-widening circle of destruction. At the current rate of loss, 40% of the world's forests will be gone by the year 2000.

But you can help reverse it. You and CARE, and a project called Care for the Earth.
Through this project, CARE plants millions of trees each year. Teaches forestry and soil conservation to poor rural farmers. Shows them how to rehabilitate and protect their land. Grow the food they need. Become self-sufficient. And proud.

Care for the Earth

We see dramatic progress. But we need your support to continue our fight.
We use your money well. With food and materials donated by governments and international agencies, your gift of $20 funds nearly $200 of land reclamation. Give $50 and we can implement almost $500 worth of care for your earth.

Please give generously, with the coupon below. There is no other program that can do so much, both for our world and for its needy people. No other program that can directly affect so many lives—including your own.

Think about it. But don't think too long. Because in the time it takes to read this ad, another 35 acres of trees will vanish.

CARE

Audubon's Mystery Birds

The pioneer American ornithologist left some loose ends

In these days of sophisticated birders, who call for illustrations of every plumage variant in order to simplify the field identification of difficult species, it is hard to imagine the state of American ornithology in the days of John James Audubon. Although many North American birds were well known to Europeans, there were no handy books about them. Audubon's archrival, Alexander Wilson, was the first to attempt to compile a definitive American ornithology but died in 1813 before finishing it. The two pioneer ornithologists met just once, by chance, in Louisville, Kentucky, in 1810. Wilson showed Audubon his first two published volumes and Audubon showed Wilson a portfolio of early drawings. Neither had known before that they shared the same ambition, but from then until Wilson's untimely death at age forty-seven, each was very conscious of his rival's activities, and suspicions and accusations of plagiarism arose.

A large number of the birds that fell to Audubon's gun were new to him, and to the best of his knowledge had not been previously described. In the first edition of *The Birds of America* (published 1827–1838), Audubon provided English and scientific names for all of them. In some instances, after examining specimens and books in London and elsewhere, Audubon learned that a species had already been named in an earlier published work. He acknowledged this in his later writings, but in most cases, he continued to believe that he had discovered a new species.

Bird watchers today are more familiar with the striking plumage differences between the sexes and age classes of many common American birds. Collection and field observation since Audubon's day have shown that many of his new species wer simply plumage variants of well-known birds. For example, hi controversial bird of Washington is an immature bald eagl The hemlock warbler, whose discovery Audubon graciousl credited to Wilson, proves to be the female of the Blackburnia warbler, a species whose brilliantly colored male was known t both authors.

Some of Audubon's discoveries remain valid, but not neces sarily as species. Five "kinds" of woodpeckers he illustrated i one plate are hairy woodpeckers from various parts of th United States (and not all are valid subspecies).

In 1822, Audubon shot a handsome duck in Louisiana that h first thought was the obscure bimaculated duck (not bemacu lated, as often spelled). After comparing his drawing with spec mens in London, however, he decided it was a new species an named it Brewer's duck, in honor of his friend Thomas Brewe At the same time, however, he conjectured that his specime was a hybrid rather than a new species, suggesting the mallar and the gadwall as possible parents. This crossing has since bee recorded many times, both in the wild and in captivity; Audu bon's guess turned out to be correct.

Five of Audubon's species have puzzled subsequent genera tions of ornithologists. Two birds, the Blue Mountain warble and the small-headed flycatcher, appear in one plate with a mis cellany of well-known species. The warbler was discovered b Alexander Wilson near the Blue Mountains of Pennsylvania Audubon never saw the species alive, but stated that his descrip tion and drawing were "taken from a specimen lent to me by th

by Kenneth C. Parkes

Audubon's illustration of what he called carbonated warblers was based on two male specimens he shot in Kentucky in May of 1811. Were they Cape May warblers in their first spring?

All photographs by AMNH

What Audubon thought was a separate species, which he named the bird of Washington, was actually an immature bald eagle.

ıncil of the Zoological Society of London, and which had
ıe from California." Its wing bars, white-spotted tail feath-
and streaked sides all suggest a wood warbler of the large ge-
Dendroica, but no species belonging to that genus combines
se characters with the sharply delineated yellow forehead
unstreaked back shown in Audubon's illustration.

Audubon tells us that in the early spring of 1808 he shot and
w a small unknown bird at Louisville, Kentucky. This draw-
was among those he showed to Wilson, who, Audubon
med, copied it and published it, identifying it as a small-
ded flycatcher, *Muscicapa minuta*, without giving proper
dit. Wilson wrote that he saw the bird in various parts of New
sey and shot one on April 14. Audubon searched that state in
ı for the species. (Of course, if Wilson did shoot one in mid-
ril it may well have been a migrant.) Audubon states that he
er saw another specimen of this species in any museum or pri-
e collection.

Several of the wood warblers that forage by hawking after fly-
insects were called flycatchers by Wilson, Audubon, and
er early authors, and the description of *Muscicapa minuta*'s
its indicates that it probably belonged to this group. But
e are known to have the combination of white eye ring and
te wing bars assigned to this mysterious species.

Many writers ascribe such discrepancies to faulty memory on
dubon's part. Although the published figure of the small-
ded flycatcher was drawn as late as 1838, Audubon states
the drawing and his description were copied directly from
original sketch and notes of 1808. An alternative explanation
the confusing characters of both the Blue Mountain warbler
the small-headed flycatcher is hybridization, which we now
w occurs among warblers more frequently than once be-
ed, often between surprisingly dissimilar parent species.
king the actual specimens, we can only guess what unions
ht have produced these unique combinations of characters,
perhaps appropriate matches will someday be found.

ome suggest the Cuvier's wren that Audubon shot in Penn-
ania in 1812 was also the result of hybridization. His illustra-
seems to combine the colors of two little birds, the ruby-
wned and golden-crowned kinglets. But the structural
racteristics of the plumage mentioned in the text—such as
"small decomposed feather covering the nostril"—are all
cal of the golden-crowned. George Watson of the U.S. Na-
al Museum of Natural History concludes that this was noth-

*traits of Audubon's Blue Mountain warbler and small-
ded flycatcher (left and right, beneath the uppermost bird)
ot match those of any known species.*

A bird Audubon called Cuvier's wren is not a wren; it most closely resembles a golden-crowned kinglet.

ing more than a golden-crowned kinglet whose crown patch w bright red rather than the normal yellow with an orange cent

Another one of Audubon's mystery birds is the carbonat warbler, whose illustration and description were based on t males Audubon shot in Kentucky in May 1811. As long ago 1832, the British ornithologist Sir William Jardine suggest that these birds were Cape May warblers, and Audubon hims postulated that his specimens were young birds from the prec ing year, "not in full plumage." In their first spring, male Ca May warblers differ from older males in that the orange-bro cheek patch is reduced or practically absent and the white wi bar is much narrower. These features exactly match Audubo plate of the carbonated warbler, so it is probably not necessary look any further for a plausible explanation.

Perhaps the most intriguing mystery bird is Townsen bunting, *Emberiza townsendi*, which Audubon named for discoverer, John K. Townsend. This is the only mystery b whose specimen still exists. It is kept in a locked cabinet in t National Museum of Natural History in Washington, wher have been privileged to examine it. Although several theor have been advanced, no ornithologist has ever ventured to id tify it definitively. The bird's general conformation agrees w that of the dickcissel (*Spiza americana*), so most authors ten tively place it in the genus *Spiza*. It certainly does not belong *Emberiza*, the genus of Old World buntings.

Although Audubon said nothing about the circumstances Townsend's discovery of this bird near Philadelphia, Tow send's notes were later published in *The Auk*, the journal of t American Ornithologists' Union. After rereading these, I ha come to believe the specimen probably represents a dickcis that lacked the normal carotenoid (yellow) pigments in its plu age, having only the browns, blacks, and grays produced by m anin pigments. Such pigment deficiencies, resulting from mu tions or failures in development, are well known in some otl groups of birds. The absence of yellow pigments, for examp produces the blue variety of the familiar green budgerigar, parakeet. The plumage pattern of Townsend's bunting (allow for the subtraction of yellow) is that of an adult female dick sel, but according to Townsend's description, his specimen wa male. Perhaps an abnormality resulted in the absence of yell pigment and, at the same time, prevented the bird from assu ing the normal plumage of the adult male. The fragile remains this bird cannot really tell us the answer.

The original specimen of one of Audubon's mystery birds, Townsend's bunting (lower left), still exists, but it has not bee definitively identified.

Brown thrashers being attacked by a black snake, an Audubon watercolor.

Painter of the Feathered Tribe

udubon and his work were one,
ived in his work, and in his work will live forever"

Phillip Drennon Thomas

wo hundred years ago this month, on then prosperous island of Santo Do-go (Hispaniola), John James Audu- was born to a French sea captain and sland mistress. Essentially self-taught ience and art, by the time of his death 851 he had left an indelible mark n American natural history and art. rges Cuvier, the founder of compara- anatomy, proclaimed that with *The ls of America*, Audubon had created most magnificent monument which yet been raised to ornithology." Audu- was a talented field naturalist with powers of observation. Nevertheless, late in his life, he had but limited wledge of the technical dimensions of thology. Although he may be the most ely recognized of America's nine- th-century artist-naturalists, he is re- nbered, not for any specific scientific ribution, theory, or idea, but rather for rt. Frequently criticized by his contem- ries for a lack of attention to scientific il, Audubon could never be accused of ng to appreciate the splendor of the s he pursued with such passion.

udubon's mother died a few months r his birth, and his father left the is- in 1789. Two years later, with a half- r who had also been born on the is- , Audubon rejoined his father, who settled in Nantes, France. In 1794, children were formally adopted by his er and stepmother. Audubon's early eriences at school in Nantes were ked by frequent absences. He later ob- ed that "almost every day, instead of g to school where I ought to have e, I usually made for the fields, where I t the day." He returned home each ning with "curiosities, such as birds' s, birds' eggs, curious lichens, flowers of all sorts, and even pebbles gathered along the shore of some rivulet." Audubon's father wished for him to become a naval officer; his stepmother, a priest. After attending a midshipmen's school at Rochefort-sur-Mer for three and one-half years, Audubon had made little progress toward a naval career other than becoming somewhat skilled at tying knots. His future as a seaman seemed limited. A persistent but undocumented assertion is that during his early years he studied in Paris with the famous French painter Jacques Louis David. If Audubon was, as he said, a "pupil of David," it apparently was for a brief period and of little lasting consequence.

So that he might avoid conscription in Napoleon's army, Audubon was sent to America in the late summer of 1803 to help supervise two hundred acres his father had acquired near Mill Grove, Pennsylvania. With imperfect English, learned from Quaker nurses who attended him while he was ill with yellow fever, he began to establish himself in America. Dressed in silk and satin, admired for his marksmanship, swimming and riding abilities, and the "elegance of his figure and beauty of features," Audubon explored the fields and forests of his new home on a branch of the Schuylkill River. Stuffed squirrels, raccoons, opossums, fishes, frogs, snakes, lizards, and birds' eggs soon adorned his room. His early years at Mill Grove were an idyllic but fleeting episode in his new American experiences: "Hunting, fishing, drawing, and music occupied my every moment; care I knew not, cared naught about them." In 1804, Audubon became enchanted with Lucy Bakewell, the seventeen-year-old daughter of his English neighbors.

Audubon continued observing and sketching the birds of eastern Pennsylvania. Fascinated by the return of phoebes to a cave on his estate, he tied silver threads around the young to see if they would return the following year. This was the earliest known case of bird banding in America and reveals Audubon's ability to design a method to answer an important question about bird behavior. A century passed before bird banding became a more common practice.

During this period Audubon began to use wires to hold freshly slain birds in position while he sketched them. This allowed him to arrange birds in more lifelike poses than could be found in mounted specimens. Audubon could not draw a particular species of bird accurately without a specimen before him, and throughout his career he enthusiastically shot birds for study and sketching. (On occasion he also ate the birds he shot.) Naturalists had traditionally prepared their sketches from stuffed specimens, but Audubon maintained "that *feathers* lose their brilliancy almost as rapidly as flesh or skin itself" and "that a bird alive is 75 percent more rich in colours than twenty-four hours after its death."

Over the years, Audubon kept progressively better field notes on the species he was studying. He often spent fourteen to seventeen hours working on a drawing and sometimes abandoned the task only when the decomposing specimen made the work unpleasant. Dissection of their stomachs enabled him to learn more about birds' feeding habits. Although he was a perceptive observer, he had difficulty portraying birds in motion. His birds in flight were among the most awkward of his representations, but this was an age when there

How To Have a Green Thumb ...Without an Aching Back!

Mulch has been the natural friend of smart gardeners since time began. Mulch is made by running weeds, used-up crops, kitchen scraps (bones and all), shrub and tree trimmings (up to 3" thick)...virtually anything organic ...*through a Kemp Shredder/ Chipper!*

Inside a Kemp, up to 54 carbon-steel blades reduce everything into *millions* of tiny pieces — *in seconds!*

Till all you can make *into* your soil. It will turn even the poorest soils into rich, dark, crumbly loam.

After crops are up, spread *Kemp-ready* mulch over your garden to prevent weed growth, hold needed moisture and feed your plants.

Ruth Stout summed up this easy, carefree way of gardening in her book, *How To Have A Green Thumb Without An Aching Back.*

Audubon labored fourteen days to paint this golden eagle with a snowshoe hare in its talons. He regarded it as one of his most successful works. The figure in the lower left corner is thought to be a self-portrait; it was eliminated in the plate for the printed version.

The New-York Historical Society, N.Y.C.

were no photographic records of such complex motion to serve as a guide.

In April 1808, Audubon wed Lucy Bakewell. Their marriage began somewhat inauspiciously when they left on a twelve-day journey to their new home in Louisville, Kentucky. While crossing the Alleghenies, their carriage overturned, and Lucy was severely bruised. In Louisville, Audubon and a partner operated a gen store for two years, but with little succ Years later Audubon observed, "We many goods and opened a large stor Louisville, which went on prospero when I attended to it; but birds were b then as now, and my thoughts were and anon turning toward them as the jects of my greatest delight. I shot, I d

ooked on nature only; my days were
ppy beyond human conception, and be-
nd this I really cared not." His first son,
ctor Gifford Audubon, was born on
ne 12, 1809. Audubon's devotion to
ds continued to divert attention from
business. "Therefore," he wrote, "my
siness abandoned me."

More momentous for Audubon's career
s his 1810 meeting with Alexander Wil-
, who shared with Audubon a love for
nerica and a passion for the nation's
ds. When Audubon met him, Wilson
s seeking subscribers at $120 a set for
American Ornithology. Years later,
ile in Great Britain promoting his own
rk, Audubon wrote, "How often I
ught during these visits of poor Alexan-
Wilson. When travelling as I am now,
procure subscribers, he as well as my-
was received with rude coldness, and
netimes with that arrogance which be-
gs to *parvenus*." Audubon remarked
t Wilson died under the "lash of a
kseller."

Wilson had even less economic success
n Audubon and was at various times in
career a poet, weaver, printer, peddler,
veyor, and schoolteacher. In March of
10, when Audubon examined the first
volumes of Wilson's work, he was at
point of subscribing to the series, but
business partner advised against it.
What induces you to subscribe to this
rk?" he asked. "Your drawings are cer-
nly better, and again, you must know as
ch of the habits of American birds as
s gentleman." Given the state of Audu-
n's business finances, this advice may
ve been as much a reflection of eco-
mic realities as a judgment of the value
Wilson's work.

Wilson, like Audubon, made technical
ors in his observations and descriptions
birds, but his ornithological knowledge
s superior to Audubon's. Yet Audu-
n's birds have a vitality, brightness, and
eliness seldom found in Wilson's small-
plates. Wilson was a self-trained or-
hologist who painted birds to illustrate
works; Audubon was a self-trained art-
who studied ornithology to comple-
nt his magnificent bird portraits. Per-
ps, as some suggest, the meeting with

SHOW YOUR KIDS
HOW A FOREST IS LOGGED

Dress 'em up in old clothes and sturdy shoes, and we'll take you all "into the woods" on a comprehensive tour of one of our logging sites.

You'll discover how lumberjacks and foresters work with computer programmers and lab scientists to sustain our forests *and* their yields forever. Your kids will go "Wow!"

We offer you tours like this because we'd like you to understand that our mills and plants and logging sites serve your interests as well as ours.

And because we're proud of them.

For a list of tour locations, write Sharon Ramsey, Boise Cascade Corporation, One Jefferson Square, Boise, Idaho 83728.

This portrait of Audubon was painted by his sons, John and Victor. A gun was one of the tools of Audubon's trade—throughout his career as a naturalist-artist, he relied on shooting birds for study. Sometimes he ate the birds he shot and offered comments on their palatability.

AMNH

Wilson initiated Audubon's dream of having his own expanding portfolio of bird portraits published.

In the summer of 1812, Audubon became an American citizen, and in November of that year, his second son, John Woodhouse Audubon, was born. Audubon also had two daughters, who died in infancy: Lucy, born in 1815, died in 1817, and Rosa, born in 1819, died in 1820.

Audubon's lack of commitment to his Louisville business was followed by almost a decade of further economic disappointments and the depletion of his wife's inheritance. He failed in the construction of a steam grist- and sawmill at Henderson, Kentucky. In an 1819 steamboat endeavor, he persuaded the brother and family of the poet John Keats to invest in his speculations. Although the details of this matter are unclear, Keats could not help thinking "Mr. Audubon a dishonest man," who made his brother believe "that he was a Man of Property." Further dissension arose when Audubon, his arm in a sling as a result of a steam engine accident, was attacked by a business associate. After receiving twelve blows from his bludgeon-swinging assailant, Audubon struck him down with his dagger. The community was enraged by Audubo method of defense, but a judge later ru that Audubon committed a "serious fense, an exceedingly serious offe Sir—in failing to kill the damned rasc

His cavalier attitude doomed Audu to failure in business, and in 1819, he jailed briefly in Louisville for debt. leased upon a declaration of bankrup with nothing left but what he deemed "humble talents," he began to do portr in black chalk of the human "head vine." Within a few weeks he was abl earn enough to rent a house in Louisv Never modest about his abilities, Au bon claimed he was even called into countryside to prepare "likenesses of sons on their death-beds" and that a c gyman had had his dead son exhume that a portrait could be made. Still, Au bon wrote, "My drawings of birds w not neglected meantime; in this particu there seemed to hover around me almo mania and I would even give up doin head, the profits of which would have s plied our wants for a week or more, to r resent a little citizen of the feathe tribe."

Audubon then moved to Cincinnati worked briefly as a taxidermist at Da

ake's Western Museum. When the omised monthly salary could not be et, he drifted south to New Orleans to ntinue painting portraits in black chalk d birds in watercolors and pastels. He ll had a difficult time maintaining him- f and provided little support for his fam- ; Lucy did not join him for more than a ar. When she moved to New Orleans, e found a position as a governess on a ntation, and later as a teacher on the tensive plantation of Jane Middlemist rcy in West Feliciana, Louisiana. For a ne, Audubon traveled to Natchez to int. There he received a brief introduc- n to the use of oils in painting from John ein, an itinerant artist.

Despite frequent economic reversals, cy continued to encourage her hus- nd. Audubon wrote, "My wife deter- ned that my genius should prevail and at my final success as an ornithologist ould be triumphant." To cultivate this ccess, Audubon had to find a method of aring the results of his studies and paint- gs of birds with a wider audience. This quired the publication of his growing rtfolio of bird paintings.

During the nineteenth century, Phila- lphia was the center for the study of nat- al history in America. Audubon arrived ere in 1824, intent on acquiring a pub- her, but his arrogance alienated some of e city's leading naturalists. When a pub- her could not be found there or in any ner American city, Audubon elected to ek support abroad.

Both he and Lucy began to save their nited resources. To provide funds for his ropean trip, Audubon taught French, ncing, and fencing. In May of 1826, he led alone for England. He had $1,700, sentially his wife's savings, to begin a oject that would ultimately last almost a zen years and cost more than $100,000. ter disembarking at Liverpool, on July , 1826, and paying a duty of two pence each watercolor that he brought into e country, Audubon, with some trepida- n, began his artistic conquest of the itish Isles.

England's interest in the natural history her former colony was strong. Bar- m's *Travels* had won a wide audience

Own an Original U.S. Gov't Mint 1893 "Columbus" Silver Half Dollar

...America's first silver commemorative type coin!

Now you can own this genuine U.S. Gov't Mint 1893 Columbus silver half dollar — America's first commemorative type coin!

February, 1985. International Coins & Currency, Inc., a national distributor of numismatic coins is offering for sale original U.S. Gov't Mint 1893 Columbus silver half dollars — America's *first* silver commemorative type coin. These are absolutely genuine U.S. legal tender coins — *not reproductions.*

Minted to commemorate the 400th anniversary of the discovery of America this vintage silver type coin has the historic distinction of being the *only* U.S. commemorative coin to honor Christopher Columbus. The "Columbus" bust observe and the Santa Maria "flagship" reverse never again appeared on any other U.S. coinage. As the 500th anniversary of America's discovery approaches, this scarce commemorative type coin should become increasingly sought after and a precious family keepsake.

A Sleeping Classic

Struck at our country's oldest mint in Philadelphia, these silver half dollars were the first "keystone" issues of America's commemorative silver half dollars — the lowest mintage lengthy coin series in U.S. history. Significant silver melts of the past and the loss of many in circulation make these "sleeping classics". Each "Columbus" silver half dollar is 31mm in diameter, contains 12.5 grams of .900 pure silver and each comes with a Certificate of Authenticity attesting to its very fine quality and genuine pedigree. This guarantee never runs out.

Because of the age, low mintage and historical significance of these coins, you might expect to pay more. But while supplies last, they are available on a first-come, first-served basis for $28 each.

ICC is offering for sale a limited number of these coins on a first-come, first-served basis: 1 coin $28; 2 coins $56; 3 coins $84, 5 coins $135 (Save $5); 10 coins $255 (save $25) and 20 coin roll $485 (save $75).

There is a limit of 20 coins per customer. Special presentation cases for individual coins are also available at $2.50 each. Your 100% satisfaction is guaranteed or you may return your order for a prompt no-questions-asked refund within 15 days (less postage and insurance of course).

To order your coins by credit card, call toll-free 1-800-451-4463, 24 hours a day, every day including Sundays. Or, if you prefer, send check or money order in full amount to: International Coins & Currency, Inc., Dept. 745, 11 E. State Street, P.O. Box 218, Montpelier, Vermont 05602. Add $2.50 for 1 coin or $5.00 for more than 1 coin to cover postage and insurance. Mr. Douglas S. Schneible, ICC's Numismatic Director is Life Member #1305 of the American Numismatic Association. All coins are availble for prompt delivery.

The wild turkey cock, which Audubon painted in Louisiana, was the basis for the first plate published in The Birds of America.
The New-York Historical Society, N.Y.C.

in England and had influenced Coleridge and Wordsworth. There was a growing romantic interest in the exotic peoples, flora, and fauna of North America. Within seven days of his arrival, Audubon had been invited to exhibit his drawings at the Royal Institution of Liverpool, where his works were displayed for more than month. More than four hundred viewe attended the second day of the exhibitio Audubon, with his long chestnut ha flowing to his shoulders, played upon h image as a citizen of the American wilde ness. He would recite accounts of his a

The State of Spaceship Earth

he message is clear and simple: the cumulative stresses of a world population approaching
ve billion are now causing global changes in natural systems. Overpopulation leads to
eforestation. Deforestation may lead to reduced rainfall. Reduced rainfall leads to famine. Such self-
einforcing cycles could soon affect people the world over. Fortunately, solutions to environmental
ress are also reinforcing; protecting one natural system leads to improvements in others. Thus
ne findings of THE STATE OF THE WORLD 1985, a study of the Worldwatch Institute, are
nportant reading for all passengers on Spaceship Earth. Learn how to become part

A print of the hooded merganser, based on a painting Audubon made in New Orleans in 1821, lies in its original shipping box.
AMNH

ventures in the wilds with Indians, Daniel Boone, bears, wolves, and frontier settlers; and if the audience's attention waned he would fill the room with wolf howls and bird calls. To the frequent questions about the dangers of bears, wolves, and foxes, Audubon coolly replied that he was never "troubled by any larger animals than ticks and mosquitoes." His "American Woodsman" image subsequently helped Audubon sell his works.

The accolades bestowed upon Audubon and his work were the first public acknowledgments of his talent that he had ever received; and while he admitted to a certain weariness from the frequent bowing that was part of receiving guests at the exhibition, he rejoiced in the praise that accompanied it. In a letter to his wife, he wrote, "I am well received everywhere, my works praised and admired, and my poor heart is at last relieved from the great anxiety that has for so many years agitated it, for I know now that I have not worked in vain."

Although he was graciously received in Liverpool, he did not find a publisher, and thus set forth for Edinburgh. There, the prominent Scottish engraver W. H. Lizars was delighted by Audubon's work and agreed to print ten of his paintings to test the market. The first plate produced was the *Wild Turkey Cock*, followed by prints featuring the yellow-billed cuckoo, p thonotary warbler, purple finch, and Ca ada warbler.

Lizars also introduced Audubon to E inburgh society. Audubon met Sir Wal Scott, whose movements he watched as they were those of "a celestial being Scott commented in his journal:

He is an American by naturalization, Frenchman by birth; but less of a Frenc man than I have ever seen—no dash, glimmer, or shine about him, but great si plicity of manners and behaviour; slight person, and plainly dressed; wears lo hair, which time has not yet tinged; countenance acute, handsome and intere ing, but still simplicity is the predomina characteristic. . . . This sojourner in t desert has been in the woods for months gether. He preferred associating with t Indians to the company of the Back S tlers; very justly, I daresay, for a civiliz man of the lower order—that is, the dre of civilization—when thrust back on t savage state becomes worse than a savag

The success Audubon had known Liverpool was repeated in Scotland's ca tal, and his head was even cast by a pron nent phrenologist. A French critic w viewed his works in Edinburgh co mented,

A magic power transported us into the fo est which for so many years this man of g

s has trod. Learned and ignorant alike
e astonished at the spectacle, which we
not attempt to reproduce. Imagine a
dscape wholly American, trees, flowers,
ss, even the tints of the sky and the wa-
quickened with a life that is real, pecu-
trans-Atlantic. On twigs, branches, bits
hore, copied by the brush with the strict-
fidelity, sport the feathered races of the
w World, in the size of life, each in its
ticular attitude, its individuality and pe-
arities. . . . It is a real and palpable vi-
of the New World, with its atmosphere,
mposing vegetation, and its tribes which
w not the yoke of man. . . . This realiza-
of an entire hemisphere, this picture of
ature so lusty and strong, is due to the
sh of a single man; such an unheard of
mph of patience and genius!—the resul-
t rather of a thousand triumphs won in
face of innumerable obstacles.

n March of 1827, the first five prints
e ready, and Audubon began the task
finding subscribers for *The Birds of*
erica. Arriving in London to sell sub-
ptions, Audubon learned that Lizars's
orists were on strike and production of
prints had ceased. The good fortune
t had been denied Audubon in earlier
rs now appeared, and Robert Havell, a
ndon engraver, assumed responsibility
the production of his works. His son,
bert Havell, Jr., played a crucial role in
production of *The Birds of America*.
eleven years, he supervised the en-
ving of the 435 plates with their 1,065
ures. As Audubon observed, the con-
uity of production was not broken for a
gle day. Given the immensity of the
ject and the quality Audubon de-
nded for his life-size prints, this was an
omplishment of the highest order.
ch plate was printed on handmade pa-
29½ by 39½ inches. (Once his task
s completed, the younger Havell emi-
ted to America and settled along the
nks of the Hudson River, where he re-
d his skills as a landscape painter.)
The major tasks of publishing *The*
ds of America, however, were left to
dubon. To find the money needed daily
pay the colorists and engravers, Audu-
n painted canvas after canvas of Ameri-
n wildlife scenes, and then, with the oil
ely dry, sold them door to door in Lon-
n. In his wolfskin coat with portfolio on

Mill Grove Farm, Pennsylvania, was purchased by Audubon's father before he settled in France. In 1803, to avoid conscription in Napoleon's army, Audubon was sent to America to help supervise the property. Thomas Birch painted this view of the farm in the 1820s.

The New-York Historical Society, N.Y.C.

his shoulder, he was a sight unrivaled on the London streets. The influential periodical *Athenaeum* stated that "he was not a man to be seen and forgotten, or passed on the pavement without glances of surprise and scrutiny . . . the clothes not made by a West-end but by a Far West tailor, the steady, rapid, springing step, the long hair, the aquiline features and the glowing angry eyes . . . and an air and manner which told you that whoever you might be he was John Audubon."

At one point, Audubon commented, he had only one sovereign left in his pocket. "I extricated myself from all my difficulties," he wrote, "not by borrowing money, but by rising at four o'clock in the morning, working hard all day, and disposing of my works at a price which a common labourer would have thought little more than sufficient remuneration for his work." It was Audubon who had to find the subscribers, prepare the drawings for the engravers, inspect the color of the prints, and deliver the prints upon completion. For the publication to continue, money had to be continually raised. The work was expensive, selling in England for 182 pounds and 14 shillings a set, and in America for $1,000. Not surprisingly, individuals would subscribe and then drop out.

In 1829, Audubon returned to Amer to prepare additional drawings and to p suade his wife and sons to join him in E land. A year later, the family moved England and began to enjoy modest pr perity. All future publications becam family enterprise, with Audubon's t sons playing a major role.

By 1830, Audubon had initiated publication of a work illustrating the bi of his homeland, but he had not really p vided any sustained discussion of their histories and appearances. Sensing t the scientific descriptions were beyond ability in English and his knowledge anatomy, he began a collaboration w the gifted young naturalist Willi MacGillivray of the University of Ed burgh. MacGillivray labored diligen with Audubon to produce the five v umes of the *Ornithological Biograph* (1831–39). In addition to providing formation about the birds portrayed *The Birds of America*, this work includ sixty brief essays entitled *Delineations American Scenery and Manners*, in whi Audubon described a quarter of a cen ry's adventures and commented upon t people and places he had encounter during his frontier days.

To collect data for the new work, Au

bon returned to America in 1831 to obta more southern specimens. With respe for his growing fame, the U.S. gover ment provided revenue cutters to aid A dubon in his work in Florida in 1831–3 The following year he chartered a scho ner and explored the coast of Labrad After another sojourn in England fro 1834 to 1836, Audubon returned to Ame ica to acquire still more specimens. T Philadelphia Academy of Science fru trated his initial attempts to study the c lection of bird skins made by Thom Nuttall and John K. Townsend on the trip across the Rockies to the Pacific, b ultimately Audubon was able to purcha ninety-three duplicate skins of these we ern birds. In 1837, on another birdi expedition, Audubon met Sam Housto president of the recently established R public of Texas.

By 1839, the publication of *The Bir of America* was complete, and the Aud bon family was enjoying unaccustome prosperity and prominence. Close to 2 sets of the work were finally sold, but t cost of this large and magnificent editi

beyond the means of most individuals. answer the needs of a broader public, dubon and his sons decided to prepare maller edition with the plates litho- phed rather than engraved. Audubon joined with John Bachman, a distin- shed Lutheran minister in Charleston, uth Carolina, to prepare a study of rth American mammals.

Bachman's knowledge of the smaller mmals was far superior to Audubon's, he often warned Audubon of the care patience needed in their work. Ever wanderer, Audubon journeyed up the ssouri River in 1843 to collect addi- nal specimens for the study. This scien- cally inconclusive trip was Audubon's major field trip. As Audubon's eyes faculties weakened in the late 1840s, son John assumed responsibility with chman for the study on mammals. But ir work, *The Viviparous Quadrupeds North America* (1845–48), never re- ved the recognition or praise that at- ded *The Birds of America*. Audubon's t years were spent at Minnie's Land, a rty-five acre estate on Manhattan is-

The great white heron in Audubon's watercolor is now considered a variant of the great blue heron. Audubon first spotted these birds in the Florida Keys, captured a few, and gave them to one of his collaborators, John Bachman, who kept them as pets.

The New-York Historical Society, N.Y.C.

land, overlooking the Hudson River. He died there on January 27, 1851.

In a letter to the prominent portraitist Thomas Sully, Audubon had observed,

> the greatest portion of my life has been devotedly spent in the *active* investigation of Nature, her beauties & her objects in granting to different individuals, classes, or species, such privileges as best suit their form, situation, or habits. This arduous task I have followed with unremitting diligence, and with a degree of industry that has caused my family and to myself more troubles than any person in Philadelphia can be aware of.

Audubon boasted to his son Victor that *The Birds of America* would become "the standard of American ornithology," but the work never achieved that distinction. As an artist, however, he attained a level of recognition never equaled by any other American wildlife artist. Audubon was consumed by his mission, and in the words of the distinguished naturalist Elliot Coues, "Audubon and his work were one, he lived in his work, and in his work will live forever."

Although Audubon had his scientific limitations, these were often shared by other nineteenth-century ornithologists. His powers of observation and ability to make taxonomic distinctions enabled Audubon to describe one new genus, twen three new species, and twelve new subs cies. The plates of *The Birds of Amer* represented almost 60 percent of the s cies in America. Audubon initiated first bird banding experiment in Ameri and in later experiments he sought to de onstrate the turkey vulture's ability to fi food through smell. Contemporary crit who assailed Audubon for his many su posed mistakes were later found to ha erred also. His famous 1827 print showi mockingbirds defending their nest agai a rattlesnake subjected him to ridicule, it was maintained that rattlesnakes did climb trees and that their fangs did bend upward at the tips. Later studies v dicated Audubon's drawing on bo counts.

With his life-size drawings of birds their appropriate habitats, Audub transformed scientific illustrations in art. Although the pressure and expense meeting the publication schedule led certain expediencies that reduced t quality of the final plates of his gre work, Audubon's watercolors and e gravings are almost always filled wi strength, action, and color. With th careful, realistic execution and consiste narrative theme, these works are the e during legacy of John James Audubon.

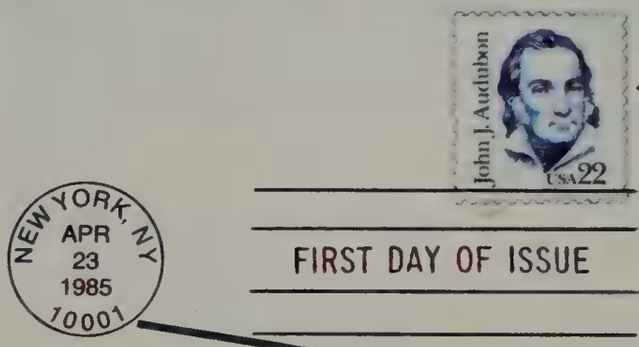
Announcing the Official First Day Cover of America's new

John James Audubon Stamp

issued by the National Audubon Society and available for just $1 each.

John James Audubon

As if born for the task, Audubon became America's greatest painter of birds.



America's new John James Audubon stamp will be issued on April 23, 1985.

The First Day of Issue postmark records the date and place where the stamp was first issued, thus certifying the new stamp as a First Edition.

First Day Cover shown smaller than actual size of 6½ by 3⅝ inches. Postmark is artist's concept.

Beautiful full-color work of art by the great American bird artist, John James Audubon.

National Audubon Society

No single person in the history of the world has contributed so much to the art of painting birds as the legendary John James Audubon.

For in a time when it was still possible to document the unspoiled wilderness heritage of America, John James Audubon made it his personal mission to capture on canvas *all* the birds that inhabited the North American continent . . . many of which have long since disappeared from the American countryside. In all, he painted more than four hundred of America's birds.

America's new Audubon stamp

Now — as a special nationwide celebration of the artistic legacy of John James Audubon — the United States will honor Audubon with a new postage stamp, during the two hundredth anniversary of his birth. To be issued on April 23, 1985, the stamp will feature a portrait of Audubon, an American who is recognized as the greatest bird artist the world has ever known.

Obtain the National Audubon Society's Official First Day Cover

To make this historic United States stamp easily available to you, the National Audubon Society — the famed conservation organization founded under the very name of Audubon — will issue its *Official* First Day Cover of the new stamp. This First Edition will be certified by the important First Day of Issue postmark Officially applied by the U.S. Postal Service.

The *Official* First Day Cover will bear the *Summer Tanager*, an Audubon painting meticulously reproduced from the famed engraving which Audubon himself commissioned in 1826, as a legacy for future generations of mankind. Significantly, many such Audubon works are presently on display at the American Museum of Natural History in New York City.

The National Audubon Society's *Official* First Day Cover of the new John James Audubon stamp is available for the modest price of just $1 each.

To order, postmark the attached Order Form by April 23, 1985, and mail it to Fleetwood, One Unicover Center, Cheyenne, Wyoming 82008-0001, which has been officially appointed by The National Audubon Society to produce the Covers and process and ship all orders.

Audubon's Coppers

The American Museum of Natural History contains many interesting hidden areas, but few are as impressive as the Audubon Hall, open only by special arrangement with the Museum's Ornithology Department. Paintings, prints, drawings, and other memorabilia of John James Audubon and his sons cover the hall's wood-paneled walls. The lighting is dim—to protect the watercolors—and the aroma of old wood permeates the room. Here, in a glass case, is Audubon's wooden palette, burnished with age. Next to it are half a dozen bird skins—some from extinct species—from Audubon's personal collection. Another case displays his guns, a brace of pistols, and a set of buckskins given to him by Indians. Several portraits of the artist hang on the walls, along with oil paintings and engravings of birds, several original watercolors for *The Viviparous Quadrupeds of North America*, and his portfolio, in which he carried prints from *The Birds of America* to show potential subscribers.

Among these Audubon treasures are a number of dull copper plates hanging high on the walls. These are some of the original engraved plates used to print the *The Birds of America*. Of the 75 or so extant plates (originally there were 435), the Museum owns 12. To mark the two hundredth anniversary of Audubon's birth, which falls on April 26, 1985, the Museum is issuing a new edition of 6 prints from *The Birds of America*, struck directly from the original plates. The subjects of these 6 plates, among Audubon's finest, are the *Wild Turkey, Male;* the *Female Turkey with Young;* the *Snowy Owl;* the *Mallard Duck;* the *Canada Goose;* and the *Great White Heron.*

In 1838, when the first edition of 435 plates was completed at Robert Havell's workshop in London, Audubon arranged to have the plates shipped to America, where they could be restruck. Although he had planned to run off 500 sets for the first edition, he sold fewer than 220 sets. Still, Audubon often expressed his intention of issuing a new edition. But a series of misfortunes, combined with a lack of funds, prevented him from carrying out his plan, and most of the plates eventually disappeared.

Twelve of the surviving plates are on display in the Museum. The details of their journey from London to Central Park West are lost to history, but a number of romantic stories have been told to explain their appearance. They were supposedly salvaged from the bottom of New York Harbor, burned in a great fire, ar rescued at the last minute while beir loaded into a furnace.

In 1839, before their transatlantic jou ney, Audubon insured the plates (or co pers, as he sometimes called them) f $5,000. An excellent account of the fac and myths surrounding the history of th plates can be found in *The Double El phant Folio*, by Waldemar Fries.

According to Fries, who did an exhau tive investigative job, the 435 plates le London in March 1839 and landed in Ne York in May. In one doubtful account, th ship carrying the plates sank in New Yor Harbor and lay there for several montl before a salvage operation could be unde taken. When they finally were hauled u to the surface, the plates were alleged

A new print of the Mallard Duck, *struck from the original copper plate in the Museum's collection*

38. Zambia Airways: Photo safaris through Zambia's game preserves and National Parks, by foot or in open Land Rover. Tours include Victoria Falls. Free brochures on tour packages and departure dates.

covered with copper oxides. We do know that Audubon consigned the plates to a "Mr. Hall's store," where they remained until 1845. In July of that year, a great fire in New York destroyed Hall's warehouse and damaged many of Audubon's plates. Shortly thereafter, Audubon wrote a letter to a friend at the Smithsonian: "We are now engaged in trying to restore [the plates] wonted former existence; although a few will have to be reengraved for use, if ever the work is republished in its original size at all." Audubon had hoped the plates would be a steady source of income for himself and, especially, for his children.

Audubon died in 1851 without having realized his plan to produce a new edition. His widow, Lucy Audubon, built a small shed (called the cave) on the family estate to store the plates. She made various attempts to sell or give the plates to national institutions, but nothing came of her efforts. By 1870, financial difficulties had forced her to consign the plates to an auction house. But the auction went poorly—no one was interested in the plates as art. In 1871 the plates were sold as scrap copper, to be melted down into bars. "There is something almost sad," the *New York Times* reported in March 1871, "that the original plates of that magnificent work, Audubon's 'Birds of America,' were recently sold in this city for their value as old copper, after having vainly sought a purchaser upon their artistic merits."

In 1870, Lucy Audubon had 350 plates, probably those not badly damaged in the 1845 fire. In the next few years, most of these plates were dispersed and lost, but a number of them showed up at the Ansonia Brass and Copper Company, in Connecticut. The company's president, William Dodge, was one of the founders of the American Museum of Natural History. There are two accounts of how some of the best plates were saved from the furnace. The first is that Dodge saw them at his refinery, recognized their value, and saved those that were in good condition.

A slightly different story was recounted by Charles A. Cowles in a letter to Ruthven Deane, published in 1908 in *The Auk*, the journal of the American Ornithologists' Union. Cowles wrote:

> Some time about the year 1873, there were found a number of Audubon copper plates among the scrap copper sent to the refinery of the Ansonia Brass & Copper Company at Ansonia, Conn., to be converted into copper bars. . . .
>
> At that time I was about fourteen years old. . . . I happened to be at the refinery watching the process of loading one of furnaces, and noted on one of the sheets copper that a man was throwing into furnace, what appeared to me to be a p ture of a bird's foot. . . . I made an imme ate but unsuccessful request to the forem of the furnace not to melt the plates; a then I appealed to the superintendent, without avail. I next brought the matter the general manager of the concern, my ther, from whom I received no encoura ment. . . . I hastened back to the works i state of mind so determined that I s ceeded in having all of the plates that h not been melted removed to a place safety. . . . The plates were subsequen submitted to a treatment which removed oxidation and then taken to the main off of the company, and to the best of my r ollection, distributed as follows: Mr. W Dodge, president of the company had a f plates sent to the American Museum Natural History, New York City, and a f plates to the Smithsonian Institutio Washington, D.C., and I think retained o or two for himself. . . . I have sent two pla to Miss M.R. Audubon. . . .

Dodge did give away the plates, Cowles wrote (some also went to the M ropolitan Museum of Art and Princet University), and he did keep "one or tw for himself; Cowles's story seems to true, though perhaps embellished. Dod

Stokes Nature Guides don't just IDENTIFY wildlife. They help you UNDERSTAND it.

DONALD W. STOKES has invented a totally new kind of nature guide. These compact, sturdily bound handbooks take you beyond field identification into the most exciting aspects of the inner lives of plants and animals. With their guidance you can actually go into unexplored avenues of natural science—with your own home ground as your laboratory and its commonly encountered species as your subjects. Whether you are exploring mating rituals of the mallard duck, the predatory behavior of ambush bugs, the teeming life under the ice of a frozen pond, Stokes Nature Guides will prove informative and inspiring, leading you and your family toward a deeper understanding of nature, and a sense of its many as yet undiscovered secrets.

LITTLE, BROWN and COMPANY

ably gave nine plates to the American seum, including four that appear in Museum's new edition: the *Snowy* , the *Female Turkey with Young*, the *ada Goose*, and the *Mallard Duck*. ria and Florence Audubon, Audubon's ddaughters, gave their two plates to Museum; one, the *Great White Heron*, so included in the new edition. Finally, 979, Cleveland Dodge, grandson of liam Dodge, gave the Museum plate nber I, the *Wild Turkey*, which ught the Museum's holdings to twelve. everal years ago, the Museum decided oin forces with a British firm, Alecto torical Editions, to create a new edi- from the Museum's best six plates. cto had recently taken on a monumen- project for the British Museum, the ting of Joseph Banks's *Florilegium*, a es of more than seven hundred copper ravings discovered in the storerooms of British Museum (Natural History). graved in the late 1700s to illustrate anical specimens collected on Captain k's voyage to Australia, the work had er been printed, and Alecto was under- ng the first edition some 200 years e." Since Alecto had considerable ex- ience in eighteenth- and nineteenth- tury copper engravings, the Museum the firm should handle the Audubon es. Thus, in 1984, six of Audubon's es returned to London for the first e in 150 years, to be cleaned, restored, printed in an edition of 125. (Curi- ly enough, the Egerton-Williams Stu- where the plates are being printed, is hin walking distance of Havell's old dio, where they were first engraved.) o print the first edition of the *The ds of America*, Havell used a common hnique of the time, although one rarely ployed on the enormous scale or size as double elephant folio. Using Audu- 's watercolors as a guide, Havell en- ved the birds and backgrounds on large ny more than six square feet) copper es. The plates were then printed in ck ink, and colorists painted over each pression with watercolors. Although dubon was delighted with Havell's gravings, he often complained about the lity of the coloring. Indeed, anyone o has had a chance to compare two of nineteenth-century prints will proba- have noticed marked variations in or. Pressed for time and money, the col- sts sometimes cut corners, especially en Audubon was away selling subscrip- ns. Writing in his usual blunt manner, dubon brought his complaints to vell: "Do let me urge you more than r to pay the strictest attention to the louring for its is doubtless through their

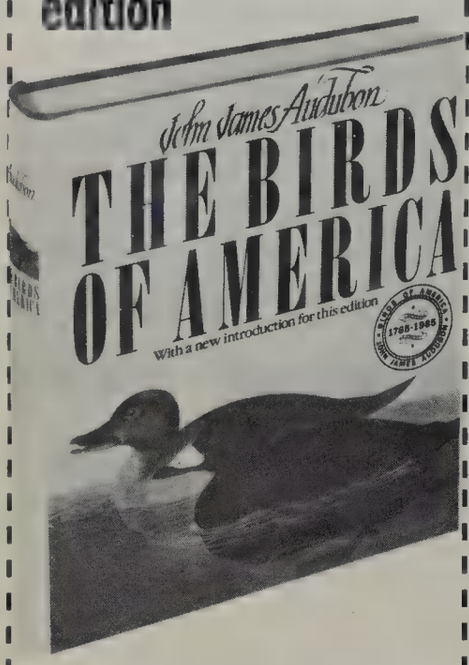
The classic Audubon collection is now available in a new commemorative edition



In celebration of the 200th anniversary of Audubon's birth, Macmillan is reissuing *The Birds of America*, with a new introduction by Robert McCracken Peck, fellow of the Academy of Natural Sciences in Philadelphia. The more than 400 illustrations in this unique one-volume work were originally part of the famed "Elephant Portfolio," first published in London in 1827. A triumphant celebration of beauty, *The Birds of America* is a matchless gift for bird lovers and collectors of fine artwork alike.

Reviews of the original edition:

"Should have a fundamental place in the libraries of all who value our American heritage."
—New York Times

"One can only call it superb."

Audubon's original watercolor of the Snowy Owl

The New-York Historical Society, N.

evident carelessness that the Work suffers so much at present." A few days after dispatching this letter, he received the proof of the Baltimore oriole and fired off another letter: "The hanging nests [are] no more like my drawing than a chimney sweep is to your beautiful wife." At one point he even had the colors bleached out of several prints.

In the present edition, Alecto hopes to realize more exactly Audubon's intentions in terms of color by referring to his original watercolors and even to actual bird specimens in the American Museum. Ornithologists from the Museum worked closely with Alecto, checking the details of coloration. Alecto's printing metho will also differ slightly from Havell's. I stead of striking the print in black an painting over—which can obscure fine engraved details—colored inks will be a plied to the plate. In this process, invente by the Dutch in the seventeenth centur the master printer works the colored ink into the engraved lines by hand *à la poupe* (with a rag dabber). Therefore, when th plate is struck, much of the color is alread laid down, resulting in a richer, deeper pri with the engraved details of feathe clearly visible. Just as in the nineteent century, a watercolorist then adds by han the details of color to each print.

Alecto will sell the edition by subscription, and the Museum has agreed not to strike any additional prints from the six plates for general sale for at least fifty years. The royalties from the edition will endow a fund for natural history in Audubon's name.

Two proofs of the new prints, the *Wild Turkey* and the *Snowy Owl*, will be on display in a new exhibition opening April 18 in the Museum. Entitled "Audubon: ence into Art," this exhibition will su quently tour the country. The Museu new edition will also be featured in Da Attenborough's upcoming television umentary on Audubon, which will ai the United States on Wednesday, A 24, at 8:00 P.M. on the Arts and Entert ment Cable Channel.

Audubon once wrote to one of his s

At the American Museum

New Magazine for Children

The Museum has announced the publication of *Faces*, a new magazine that explores anthropology, archeology, and cultures of the world. Geared for children eight to fourteen years old, *Faces* includes short articles, games from around the world, puzzles, photographs, and tales and legends. Each issue is devoted to a single theme; among these are dragons in cultures around the world, myths and legends of the Hopi Indians, and African gold. *Faces* is published by Cobblestone Publishing in cooperation with the Museum. To subscribe, send $16.50 ($13.95 for Museum members) to *Faces*, 20 Grove Street, Peterborough, NH 03458.

Audubon Exhibition

A new exhibition on the great American naturalist John James Audubon will open on April 18 in the Naturemax Gallery. *Audubon: Science into Art* includes a wealth of material from the Museum's substantial holdings of Audubon iana—including some of Audubon's watercolors and oil paintings, original letters and manuscripts, bird specimens, palette and guns, and buckskins. Also on view will be two prints from the Museum's new edition of six plates from *The Birds of America*. After July 21, the exhibition will be presented at a number of other museums in the United States.

Man and Nature Lectures

In April, Nobel laureate Gerald Ed man will deliver the *1985 Mack Lip Man and Nature Lectures*. In a series five lectures entitled "The Sciences Recognition," Edelman will explore t evolution of life from simple-celled orga isms, the growth of an embryo from a f tilized egg to a functioning adult, and t most recent theories on the nature a function of the human mind. Edelma lectures will draw on his research on e bryonic development and the organiz tion of the higher brain functions.

All lectures will take place in the Au torium at 7:00 P.M. On April 8, the topic "Evolution: Adaptation and Organiz Complexity"; on April 10, "Developme tal Biology: Molecular Bases of Anim Form"; on April 12, "Immunology: Sele tion and Instruction"; on April 15, "Ne robiology: Categorization and Learning and on April 17, "The Grand Loop: Ev lution and Awareness." Tickets for the s ries are $10 for members, $20 for no members. Call the Membership Office (212) 873-1327 for more information.

Maya Exhibition

Maya: Treasures of an Ancient Civ lization, a major new exhibition of 27 Maya artifacts, opens in Gallery 3 April 26. Following its appearance at t Museum, it will travel to the Los Angel

ht of the Bumblebee

n Saturday, April 27, at 2:00 P.M., I
tori di New York will present *Choral
sic of Birds and Bees and Bugs*, a con-
in celebration of flying creatures. The
ings for these pieces span several cen-
es, various languages, and a number of
posers. The free program will take
e in the Kaufmann Theater.

estial Rhythms

On May 1 and 2, the Hayden Planetar-
will present concerts featuring elec-
ic music. Accompanied by an array of
rs and special effects, three Planetar-
musician-composers will play selec-
s from "Star Wars," "The Right
ff," Pachelbel's "Canon in D Major,"
several original works. Tickets are $8;
information call (212) 873-5714. Also
he Planetarium are *The Violent Uni-
se*, *Wonderful Sky*, and *Heavy Laser*.

mals Animals

The World of Animals, a family pro-
m for members only, will take place on
nday, April 14, at 11:00 A.M., and 1:00,
0, and 4:00 P.M. Naturalist Bill Robin-
will be joined by a number of live crea-
es, including a spiny hedgehog, a
hbaby, a hawk, an eagle, and a pere-
ne falcon. The program is free, but you
st register in advance. Call (212) 873-
7 for information.

dubon Program

On Wednesday, April 24, at 8:00 P.M.,
Arts and Entertainment Cable Net-
k will broadcast "Audubon." Written
narrated by David Attenborough, the
gram will focus on the creation of *The
ds of America*. A segment was filmed
he Museum, and coverage is given to
Museum's new edition of six plates
m *The Birds of America*.

LET THE REAL EXPERTS SHOW YOU

THE AFFORDABLE LUXURY THAT MADE OUR

ORIENT

TOURS NUMBER ONE

1985 is your year to see the highlights of the Orient and Southeast Asia with the number one tour company to the Far East. Our Orient Escapade® escorted tours give you a choice of 6 itineraries from 15 to 23 days. For example, our 15-day tour costs only $1900, complete with air from the West Coast. Included are elegant hotels, American breakfasts, Dine-Around dinners, cultural shows and more. This year we added Burma to one tour and Japan's TSUKUBA EXPO '85 to another. Send for our free color brochure for the details. Then be sure to see your travel agent.

NOVA SCOTIA

Count 'em! Over 200 bird species live here.

You can see bald eagles nesting around the Bras d'Or lakes in Cape Breton. (Maybe relatives to the young birds given to the US Wildlife Service for their re-stocking programs.)

Osprey soar and swoop above McNabs Island and along the South Shore. Cormorants stand guard at Pictou, and you'll find a fascinating collection of shore birds patrolling Evangeline Beach.

However, the mecca for bird watchers is Briar Island off Digby Neck. Here, particularly in late summer and fall, the whole area is alive with birds of every description, resting and feeding before continuing their incredible journeys.

Come and take a look for yourself. Your U.S. dollars are worth 25%-30% more up here. World-class ferries sail between Portland and Bar Harbor, Maine and Yarmouth in Nova Scotia.

parts of Madagascar, Botswana, Peru, and Australia, according to predictions by Edward M. Brooks, an authoritative meteorologist and eclipse observer.

Although it is still very dim and distant, the comet has been under observation since October 16, 1982, when it was first spotted on its current approach toward the sun. The spotters, David Jewitt, now of the Massachusetts Institute of Technology in Cambridge, and G. Edward Danielson, of the California Institute of Technology in Pasadena, found Halley with the 200-inch telescope at Palomar Observatory. Theirs was the first sighting of the comet since 1911.

Jewitt, Danielson, and other astronomers, who have reobserved Halley on numerous occasions with advanced electronic detectors, found that it is undergoing major changes in brightness. The investigators are trying to account for those unexpected changes, but as yet there is no accepted explanation.

Besides monitoring brightness changes, astronomers have been trying to detect the comet's coma, or atmosphere. According to the so-called dirty iceball theory, the permanent body, or nucleus, of a comet is a rotating solid ball of frozen gas, interspersed with microscopic rock dust particles. As a comet approaches the sun, solar heat turns the frozen matter near the surface of the nucleus to gas, thus producing the coma. Then, when the comet's orbit takes it far away from the sun, the coma is expected to dissipate as its constituent gases stream out into space and are not replaced.

The nucleus of a comet shines by reflected sunlight. Accordingly, the spectrum of the nucleus is only the sun's spectrum and there is no direct evidence of the nucleus' composition. When a coma is present, however, astronomers can observe its spectrum and determine which gases are present and in what amounts. By timing when the coma first forms, investigators can determine when the nucleus begins to release significant amounts of gas. Then, by obtaining spectra of the coma at subsequent intervals, they can monitor how its chemical composition varies as the comet approaches and rounds the sun. From that information, they try to elucidate the processes that govern the interaction of a comet with solar radiation. That's why observers have been looking for signs that the coma has formed on Halley's present approach toward the sun. If Halley did have a coma on January 4, 1984, when Jewitt and Danielson again photographed it from Palomar, it was too faint to be detected. At that time, the comet was still 760 million miles from the

Investigators believed that the com Halley's comet had finally attained tectable proportions on September 1984, when the comet was about 577 lion miles from the sun. At least, th what two astronomers from the Univer of California at Berkeley reported. T announced then that they had found coma with the 158-inch telescope at Peak National Observatory in south Arizona. One of the Berkeley astr mers, Stanislav Djorgovski, noted, "" must be one of the most distant co ever detected from the ground." Abo month later, however, astronomers at University of Hawaii, in Honol scanned the comet with an 88-inch t scope with less success. One of them, M. Pasachoff of Williams College, Massachusetts, told me that they found no obvious sign of a coma. Perh a coma is a variable phenomenon t comes and goes until it becomes f formed when the comet is near the su perhaps Halley was still so faint in S tember and October of 1984 that even perienced observers could reasonably agree on what was or was not visible.

The unexpected brightness changes Halley's comet might be related to the fering results of the groups looking for

ıa. One group apparently found it in tember, while another saw no hint of it October. A bright coma is obviously er to detect than a faint one; it is even sible that the changes in brightness are to the formation and dissipation of porary comas, resulting from bursts of emission from the nucleus. Thus, en Djorgovski detected the coma on tember 25, he and a Berkeley colgue found that the comet was 50 to 100 cent brighter than expected.

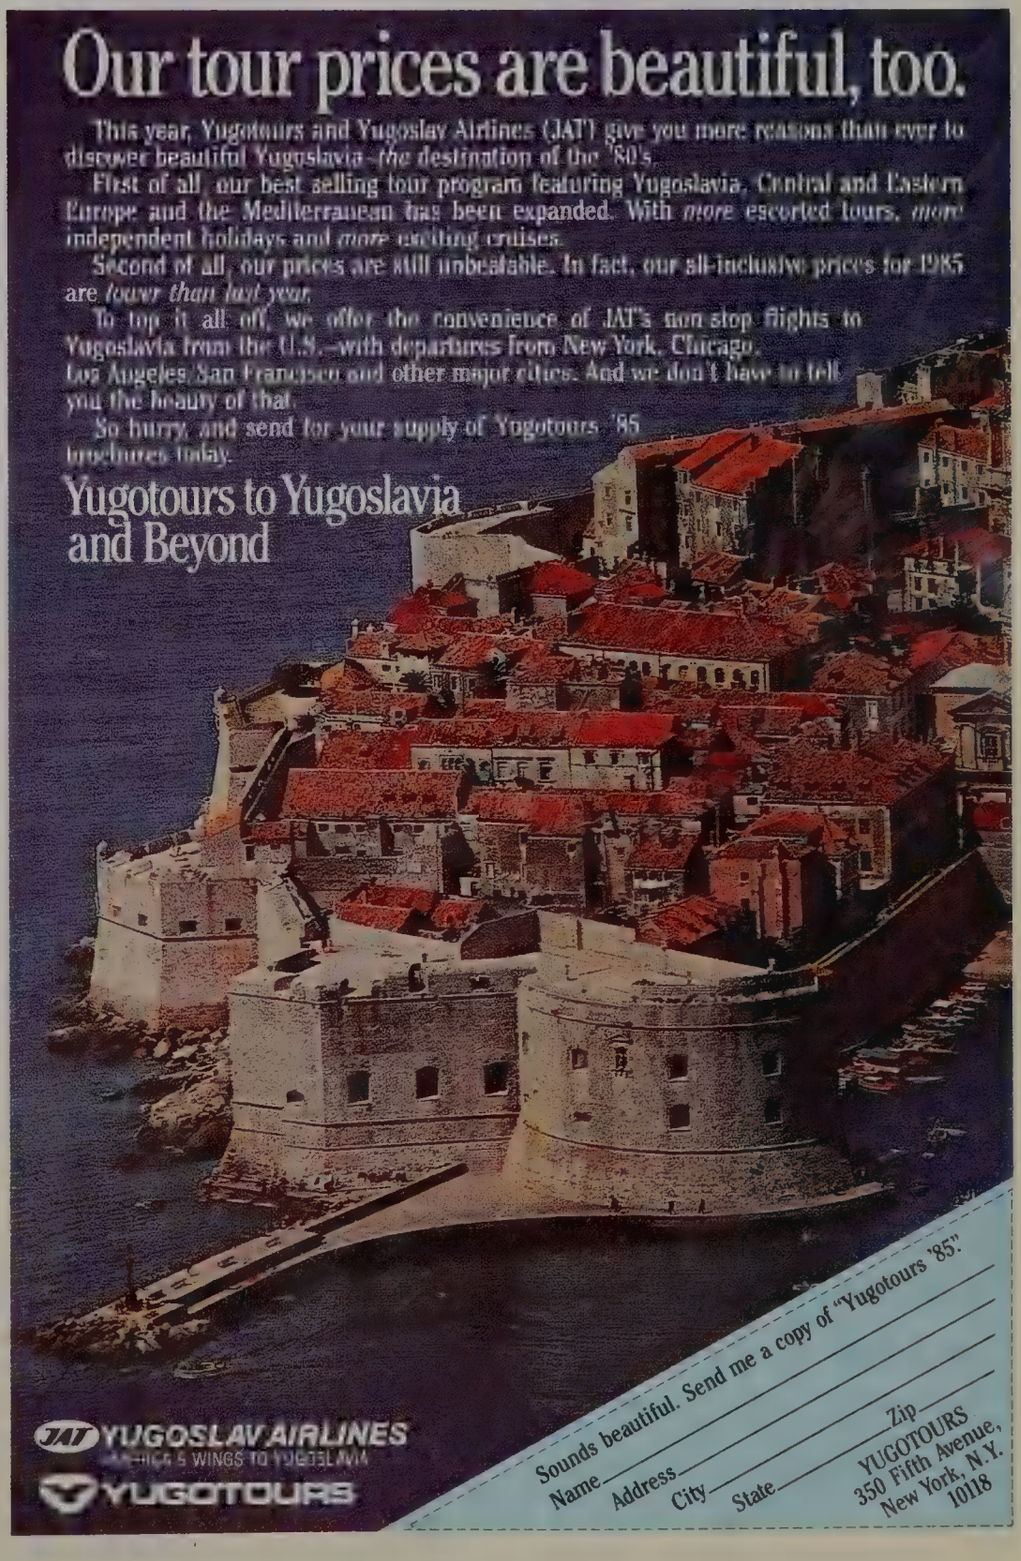
On the other hand, the unexplained ghtness changes of Halley's comet may e nothing at all to do with a coma. Inad, some astronomers propose that Hals recent brightness changes may be evnce of bright and dark areas on the net's nucleus.

f there is no coma—or at least not a ght, well-developed one—then the ghtness of the comet would depend on reflection of sunlight by the nucleus. If nucleus has unevenly distributed ght and dark areas, then as it rotates it uld reflect sunlight in varying amounts l would thus seem to brighten and fade iodically. If such is the case for Hal's comet, we might hope to determine rate at which its nucleus is turning by dying its brightness changes. Brights changes might also tell us about the pe of the nucleus. For example, a erical nucleus with a uniformly reflect surface (that is, no contrasting bright l dark areas) would not vary greatly in ghtness except in response to changes ts distance from the sun and the earth. t if Halley's nucleus were, say, oblong, n there might well be pronounced ghtness changes as it alternately sents its long and short sides toward the th, even if the nucleus surface is a unimly bright reflector.

Among the research groups that have en monitoring Halley is a team of six nch astronomers who observed the net with the 142-inch Canada-France-waii telescope on Mauna Kea during bruary 2–4, 1984, when Halley was out 739 million miles from the sun. ey reported detecting "rapid recurring reases" by up to about a factor of six in brightness of the comet. The increases med to recur at intervals of about enty-four hours and eighteen minutes, e or take twenty minutes. As one possi explanation, the French team sugsted that Halley's nucleus might have e very dark hemisphere, "like a tiny niature of the Saturnian satellite petus" (see "Iapetus, Saturn's Mysteris Moon," *Natural History*, October 84). The French measurements are difult to interpret because they are compatible with rotation rates as rapid as one turn per eight hours and six minutes and as slow as one turn per forty-eight to fifty-one hours. Furthermore, the French astronomers concluded that, rather than having a dark hemisphere, Halley's nucleus might be dark overall, but with a few large white regions.

Pronounced brightness changes in Halley have also been measured by astronomers at the European Southern Observatory on Cerro La Silla, in Chile, and by Jewitt and Danielson, at Palomar. A detailed analysis of many of these measurements by Zdenek Sekanina, an authority on comets and meteors at the Jet Propulsion Laboratory in Pasadena, led him to conclude that the rotation rate of Halley's nucleus is slower than one turn per day. He speculated that the large brightness changes may be due to the intermittent expulsion of electrically charged dust from the nucleus or to light reflecting from thin plates of ice on the nucleus. Such plates have been formed in laboratory experiments simulating a cometary environment. If present on the nucleus, the little plates would reflect sunlight as if they were mirrors, rather than in the manner of ordinary rough surfaces.

Further observations may help to determine the cause of Halley's brightness changes, but it seems to me that once the coma is fully formed, changes of the kind already observed may become less pronounced (if indeed they continue to occur)



Our tour prices are beautiful, too.
This year, Yugotours and Yugoslav Airlines (JAT) give you more reasons than ever to discover beautiful Yugoslavia–*the* destination of the '80's.
First of all, our best selling tour program featuring Yugoslavia, Central and Eastern Europe and the Mediterranean has been expanded. With *more* escorted tours, *more* independent holidays and *more* exciting cruises.
Second of all, our prices are still unbeatable. In fact, our all-inclusive prices for 1985 are *lower than last year.*
To top it all off, we offer the convenience of JAT's non stop flights to Yugoslavia from the U.S.–with departures from New York, Chicago, Los Angeles, San Francisco and other major cities. And we don't have to tell you the beauty of that.
So hurry, and send for your supply of Yugotours '85 brochures today.

DOMINIC CAPEZZA • (212) 683-1145
Greenland Cruises, Inc. 10 Park Avenue, NYC 10016

and will be correspondingly more diffic to study from the earth. Observatio made from space might help solve t mystery.

Two Soviet interplanetary spacecra *Vega 1* and *Vega 2*, launched in Decemb 1984, are en route to Halley by way of t planet Venus. After dropping probes off Venus, they will continue toward t comet and pass it in March 1986, wh they will send photographs and other da including measurements of dust partic made with an American instrument, ba to Earth. This summer, the Europe Space Agency (ESA) and Japan will a launch spacecraft toward a March 19 rendezvous with Halley. One of the spacecraft, particularly the ESA prob Giotto, which is expected to approa Halley's nucleus most closely, may get t information necessary to explain t brightness changes. If the nucleus is bac out of round or if there are large dark a bright areas on the nucleus, as suggest by the French astronomers, then a pe scope-shaped electronic camera carri on Giotto has a good chance of phot graphing them.

Although NASA is not sending a pro to Halley's comet, it is actively involved studying Halley as well as other come NASA's International Cometary E plorer (ICE) will become the first probe pass through a comet when it reach Comet Giacobini-Zinner on Septemb 11, 1985. The Soviet and ESA spacecra controllers will be watching this eve with much interest, for if high-speed du particles from Giacobini-Zinner dama or destroy ICE, there would be obvio consequences for the targeting of the cra en route to Halley. (Halley is believed be a much dustier comet than Giacobi Zinner.) The foreign controllers mig then choose to steer their craft past Hall at greater distances than planned present. On the other hand, if ICE su cessfully penetrates Giacobini-Zinner tail, the measured data will compleme the studies planned for the Halley probe

In February 1986, when Halley brightest, viewing conditions on Earth w be poor, but as Halley nears the sun in la January 1986, NASA astronauts will dro a special Halley-observing satellite into o bit around the earth from the space shu tle *Challenger*. That satellite, called *Spa tan Halley*, will be programmed b physicists at the University of Colorado make spectroscopic observations of Ha ley's coma and tail in ultraviolet light fo about forty-eight hours. Afterward, *Cha lenger* will take the satellite back on boar for return to the ground. At the same tim continuing through March, the sun-ol

ing satellite *Solar Max*, which was re-ed in space by a shuttle crew in April '4, will monitor Halley with a spec-neter and a coronagraph, a device in-ded to photograph faint features de-e the glare from the bright solar disk. d although the comet may be near or ind the sun as seen from the earth, h is not the case from the vantage point he planet Venus. Accordingly, Halley be monitored by the U.S. spacecraft *neer Venus Orbiter*, which has been cling Venus since 1978.

When the Soviet, ESA, and Japanese bes visit Halley in March 1986, there be four trained astronomers among a w of six orbiting the earth in a U.S. ce shuttle. Two of them, drawn from ranks of full-time researchers rather n from the corps of astronauts, will op-te three telescopes equipped with so-sticated instrumentation and located in shuttle payload bay. Looking at live vision pictures from the payload, the cialists in the shuttle's cabin will aim telescopes at specific parts of Hal-s comet for spectroscopic, photo-phic, and polarization measurements; smaller cameras mounted with the escopes will take wide-angle photo-phs of Halley's tail.

While all of the above is under way, usands of astronomers and millions of er people will be trying to watch Halley m the ground. Except for those situated he best viewing locations in the South-Hemisphere in April 1986, most per-s will need information and perhaps in-uction on how to spot the comet, since it l not be a prominent sight from most ces. (This is a tricky subject. For exam-, in January 1986, with the comet in the thern sky, the best viewing locations l be cloud-free mountaintops in the rthern Hemisphere.)

f you are among the would-be Halley wers, and I hope you are, nearly every al planetarium, science museum, and lege astronomy department will have ormation available by the fall of 1985, hey do not have it already. Where view-conditions permit, such organizations, ng with local amateur astronomy clubs, y sponsor public viewing sessions. If u are not yet in touch with astronomy re-rce groups in your own region of the es just mentioned, now is the time: lley's comet will not come again until 61.

ephen P. Maran is a senior staff scien-in the Laboratory for Astronomy and lar Physics at NASA's Space Flight nter in Greenbelt, Maryland. The opin-s expressed here are his own.

How to buy the finest Safari without getting skinned.

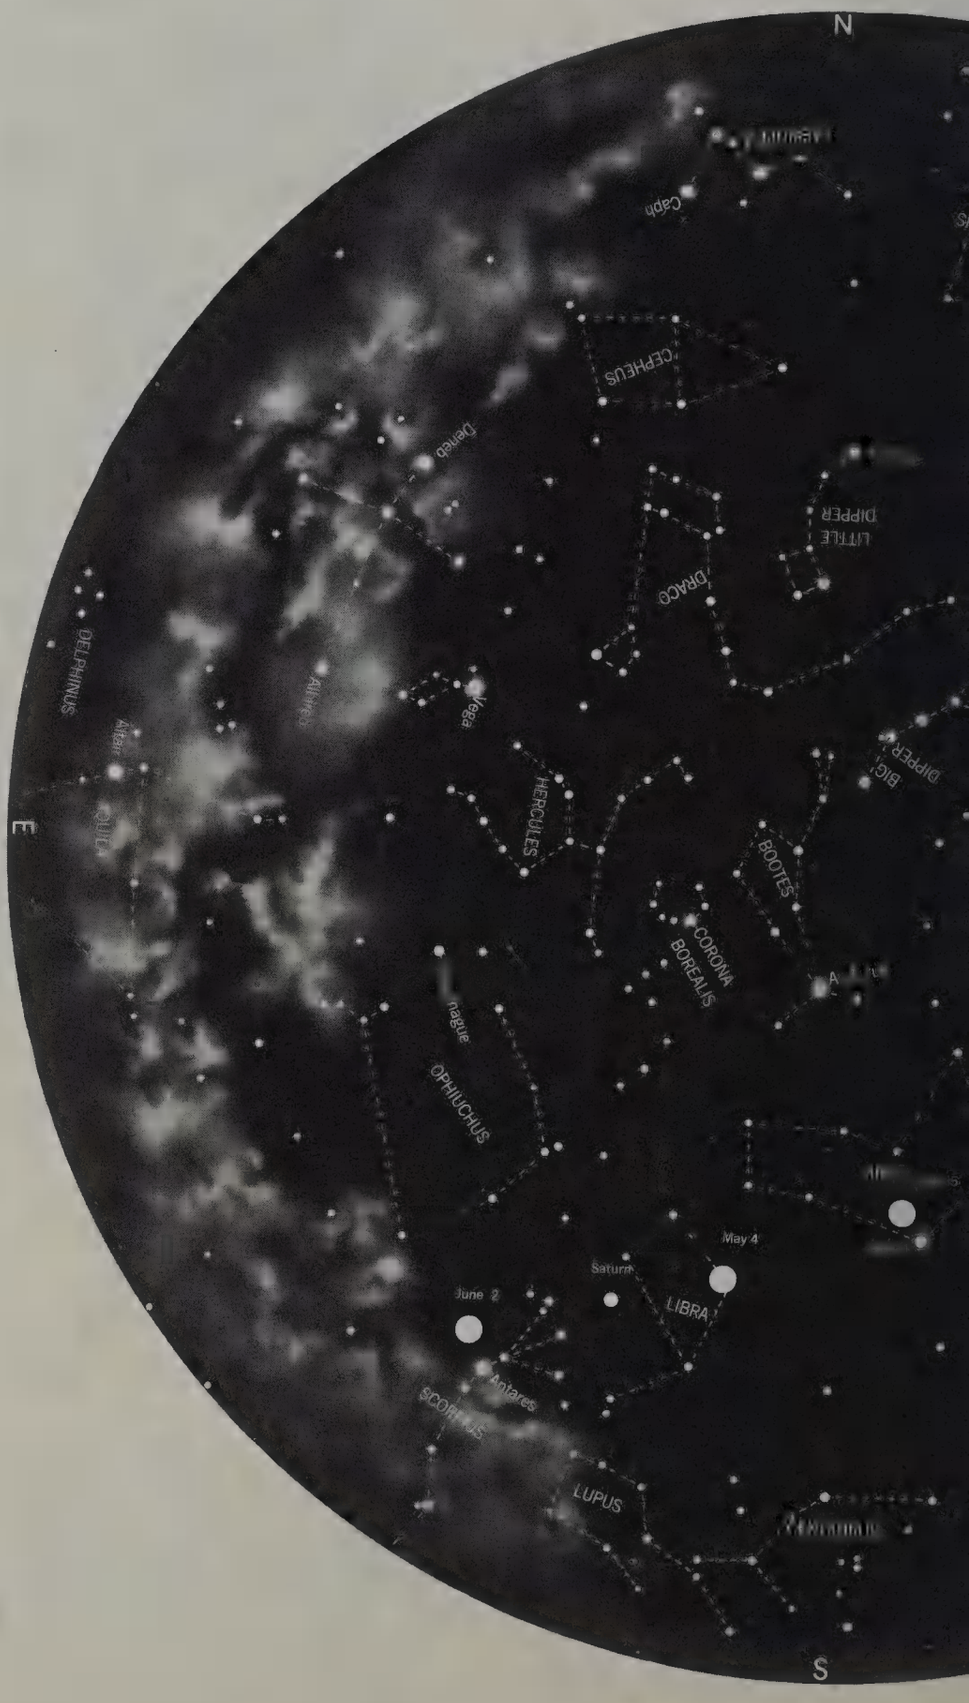
Stellar Early Risers

by Thomas D. Nicholson

Evening skies are barren of planets in April. Only Mars remains east of the sun (to its left at sunset), but it is dim and low in the early evening, as it moves from Aries into Taurus. There is an evening moon at the beginning of the month; during the last week it will help trace out the spring stars. Two morning planets, Saturn and Jupiter, will rise earlier night by night and spend much of the dark hours above the horizon. Saturn is up soon after 10:00 P.M., earlier at month's end, in Libra near the bright stars that form the head of the celestial scorpion. Jupiter, in Capricornus, rises about three hours past midnight on April 1, but two hours earlier at the end of the month. Both planets are up at dawn: Jupiter very bright in the southeast; Saturn to the west. Toward the end of April, Mercury and Venus make their presence known as morning stars, after passing between the earth and the sun early in the month and emerging from the sun's glare before sunrise. Mercury's morning appearance isn't good in the spring, but it may still be seen low in the east before



The spring Sky Map shows the sky for the months of April, May, and June from latitude 40° north at the evening hours given below. To use the map, hold it vertically in front of you with north (N) at the bottom, and match the lower half of the map with the stars you see when you face north. As you face in other directions, roll the map to bring the corresponding compass direction to the bottom of the map.

The stars move west continuously during the night. By morning (before dawn) stars on the western half of the map will have set, those on the eastern half will have moved into the west, and new stars (those of the fall evenings) will have risen in the east. The map represents the sky at about 2:00 A.M. on April 1; 1:00 A.M. on April 15; midnight on April 30; 11:00 P.M. on May 15; 10:00 P.M. on May 31; 9:00 P.M. on June 15; and 8:00 P.M. on June 30. Add one hour for daylight time. The map can be used for an hour or more before and after the times given.

Celestial Events

Speak French like a diplomat!®

What sort of people need to learn a foreign language as quickly and effectively as possible? *Foreign service personnel,* that's who.

Now you can learn to speak French just as these diplomatic personnel do—with the Foreign Service Institute's Basic French Course.

The U.S. Department of State has spent thousands of dollars developing this course. It's by far *the most effective way* to learn French at your own convenience and at your own pace.

The Basic French Course consists of a series of cassettes and an accompanying textbook. Simply follow the spoken and written instructions, listening and repeating. By the end of the course, you'll be learning and speaking entirely in French!

This course turns your cassette player into a "teaching machine." With its unique "pattern drill" learning method, you set your own pace—testing yourself, correcting errors, reinforcing accurate responses.

The FSI's Introductory Basic French Course comes in two parts, each shipped in a handsome library binder. Part A introduces the simpler forms of the language and a basic vocabulary. Part B presents more complex structures and additional vocabulary. Order either, or save 10% by ordering both:

☐ **Basic French Part A.** 12 cassettes (15 hr.), and 194-p. text, $125.

☐ **Basic French, Part B.** 18 cassettes (25 hr.), and 290-p. text, $149.

(Conn. and N.Y residents add sales tax.)

TO ORDER BY PHONE, PLEASE CALL TOLL-FREE NUMBER: **1-800-243-1234**

To order by mail, clip this ad and send with your name and address, and a check or money order — or charge to your credit card (VISA, MasterCard, AmEx, Diners) by enclosing card number, expiration date, and your signature.

The Foreign Service Institute's French course is unconditionally guaranteed. Try it for three weeks. If you're not convinced it's the fastest, easiest, most painless way to learn French, return it and we'll refund every penny you paid. Order today!

116 courses in 39 other languages also available. Write for free catalog. Our 12th year.

dawn. Try to find Venus first; even though it is not placed much better than Mercury, its brightness makes it much easier to find. If you see it in late April, look carefully below it and you may find Mercury. The view of Venus will improve in May.

Events in the calendar below are given in local time unless otherwise indicated.

April 1: A waxing gibbous moon is well up by dusk (visible in the afternoon if skies are clear). Beneath it is Regulus, Leo's bright star. The circular group of dim stars in which the moon is nestled forms the Lion's head.

April 2: The moon is east (left) of Regulus, and fatter.

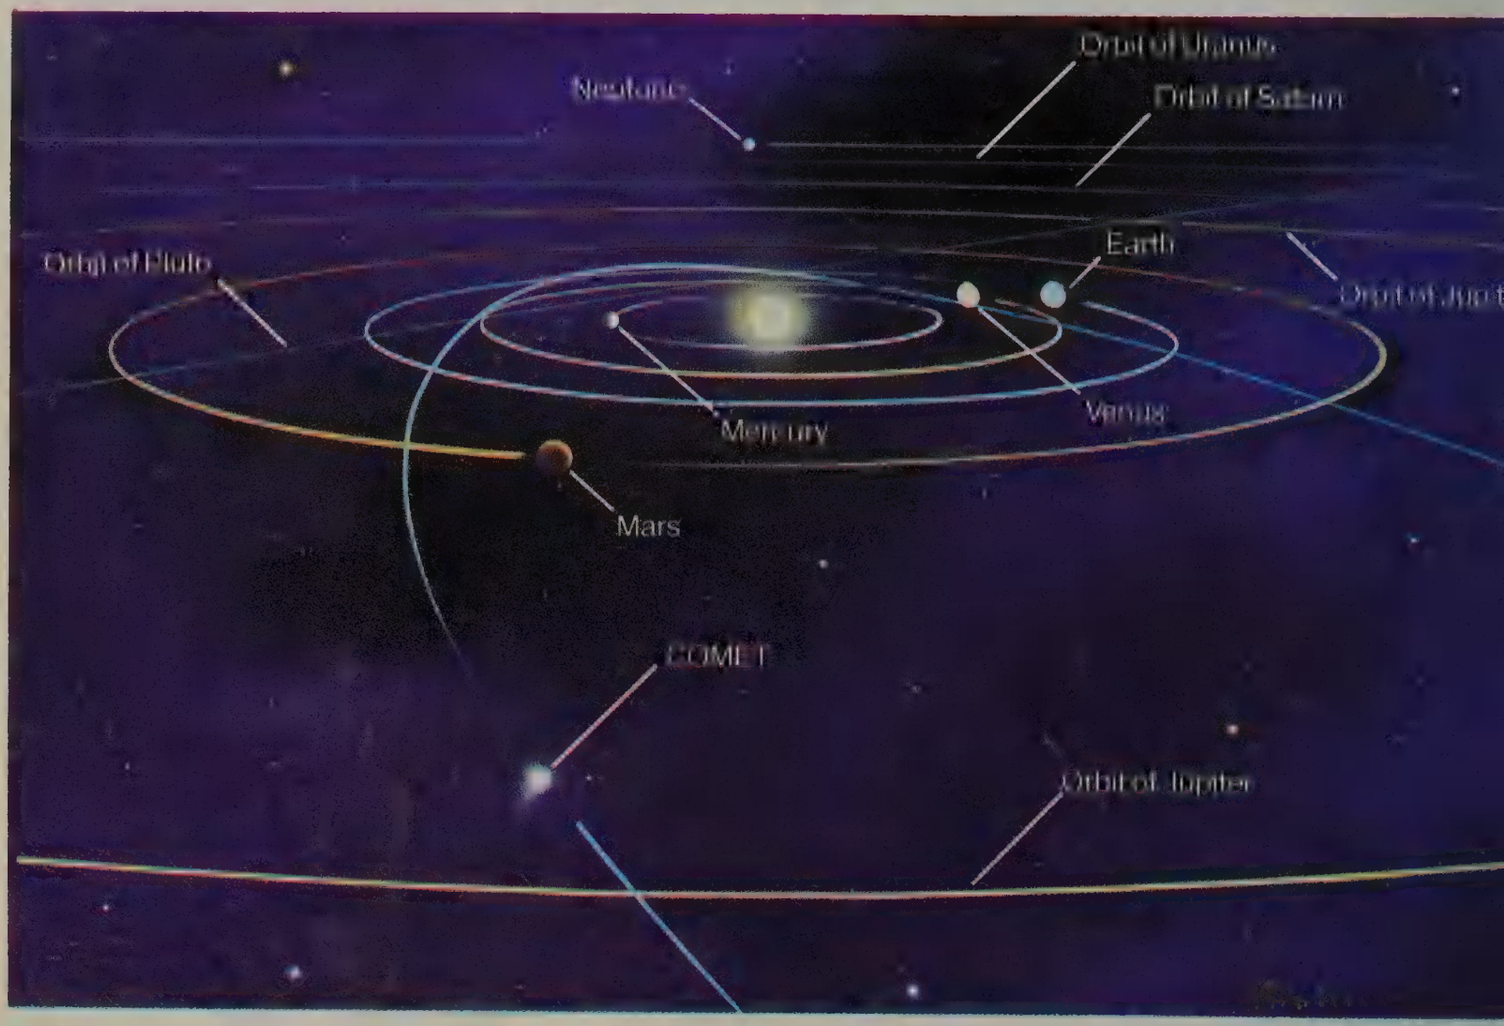
April 3: Venus and Mercury move in tandem between the earth and the sun (inferior conjunction), leaving the evening to become morning stars.

April 5: Full moon (at 6:32 A.M., EST) is in Virgo. Spica is the bright star to its left. Perigee moon (nearest the earth) comes just six hours past full and will surely fect tides tonight and tomorrow, ad strength to the full moon's spring Watch out for flooding in coastal areas pecially if the winds are strong and f the right direction.

April 6–7: The waning gibbous m slips into Libra, approaching Saturn, bright object to the east. On the nigh the 7th it passes below Saturn.

April 8: Moonrise isn't until after 1 P.M. The reddish star rising below

Halley's Comeback



In the beginning of April, as it races to perihelion (February 9, 1986), Halley's comet is 28.8 million miles closer to the sun than it was a month ago, but it is 22.3 million miles farther from the earth. (The earth and the comet are actually separating in April.) The earth's orbital motion takes it away from the comet until early May, then rapidly toward it again.

The illustration above depicts the solar system's inner planets and Halley's comet as they will appear on April 25, when the comet, racing along in its orbit at about 39,800 miles per hour, is slightly less than 400 million miles from the sun and 454 million miles from the earth. Its position is still somewhere between Jupiter's orbit, which it passed in January, and Mars's orbit, which it will pass in late November. Of course, the comet is nowhere near either planet at the time it moves past their orbital pa Because of its inclined orbit, Halley's comet is well below plane of the planetary system until November 1985, when its bit cuts through the plane from south to north. In April, i nearly 100 million miles south of the solar system's central pla

Note in the illustration that we have come in closer to the c tral solar system than our view in March. Now you can see comet's retrograde orbit (clockwise around the sun as viewe from above), which is unlike the easterly (counterclockwi movement of the earth and the other planets. Because they mo in opposing directions, the earth and Halley's comet will alt nate between approaching and receding from one another s eral times over the next year.

noon is Antares, in Scorpius. Saturn is to heir right and higher.

April 9–11: The waning gibbous moon pends the night in Sagittarius, rising after nidnight on the 9th and later the next two ights. Last quarter is at 11:41 P.M., EST, n the 11th.

April 13: Jupiter is the very bright ob-ect near the morning moon, from about :00 A.M. until dawn.

April 15: Mercury resumes its normal easterly) motion.

April 17: The moon is just below the ernal equinox about dawn, and Venus is bove and to its left. This may be the last norning view of the moon during this cy-le of phases and the first one of Venus as morning star this spring. To find Venus, ook after dawn to where the sunrise rightens the sky. The planet will improve n successive mornings (higher at each awn), but the morning moon is on the ay out.

April 19–20: Apogee moon (farthest om the earth) occurs at about noon, ST, on the 19th; new moon will be at 2:22 A.M., EST, on the 20th.

April 22: There are three events in to-ay's calendar. First, Venus ends its retro-rade motion and resumes a normal east-rly drift through the stars. It rises bright nd early this morning but it will be diffi-ult to observe. Second, the moon covers lars as it passes by the planet at 8:00 M., EST, but this is a daylight event for e southern Atlantic basin, where the oc-ultation takes place. Third, a young cres-ent moon makes its first appearance in is cycle of phases, in the west, setting at vilight. Look high in the east for the yrid meteor shower, which peaks about 00 A.M., producing some fifteen meteors n hour.

April 24: The crescent moon is easier to e tonight, midway between Aldebaran n Taurus), which is below and to its left, nd Pollux and Castor, above and to its ght. Moonset occurs at about 11:00 P.M.

April 25–26: The moon is in Gemini oth nights as it grows to first-quarter hase (half moon). On the 26th it forms a reesome with the twin stars Pollux and astor.

April 27: First-quarter moon (at 11:25 M., EST) is in Cancer. After midnight night (the 28th), clocks should be set ead one hour in communities that ad-st to daylight saving time.

April 28–29: The gibbous moon moves o Leo. Watch it slide toward the star egulus during the night of the 28th. By e night of the 29th, it will be past Regu-s, moving away from it to the left.

April 30: The moon moves from Leo o Virgo.

Organize and decorate with the beauty of natural beech wood stackable shelving

Imagine buying tough, sturdy beech wood shelving at a price you would expect to pay for plastic!

The Spacemaker Stack-A-Shelf® is so versatile it fits comfortably in any room or office. . .even in a closet. And best of all, it sets-up in seconds without tools!

Get things organized and out of the way. From toys to plants, from stereo equipment to books. . . everything has its place on these beautiful space-making units.

Sets up in seconds without tools!

Remove the unit from its flat carton, open the hinged sides, and the hinged shelves practically fall and lock into place.

Natural beech wood is attractive unfinished, so the unit can be used immediately (of course, you can finish it if you prefer).

Each free-standing unit is 27¼"w x 11½d" x 37"h and is designed to interlock and stack securely. This means you can easily create your own wall unit. And if you move, just fold them down and take them with you.

Design your own shelving arrangement in minutes. . .

RATES AND STYLE INFORMATION

The following new rates are effective with the July 1985 issue:
$2.50 per word; 16 word ($40) minimum. *Display classified* is $275 per inch. All advertisements must be prepaid. Rates are not structured for agency or frequency discounts. All advertisements are accepted at NATURAL HISTORY's discretion. Send check/money order payable to NATURAL HISTORY to: The Market, NATURAL HISTORY Magazine, Central Park West at 79th St., New York, NY 10024. Please include your personal address and telephone number, issue preferred, and suggested heading. Deadline—1st of the month, two months prior to cover date (the January issue closes Nov. 1). Camera-ready art is required for display ads. A tearsheet or copy of the page with your ad will be sent upon publication.

Friends and Anemones

Clownfish, happy looking fish of the genus *Amphiprion,* live symbiotically with deadly stinging sea anemones. Benefits include protection from predators and food (scraps of fish or algae). In return, clownfish occasionally feed their anemone by shoving food captured in the surrounding area into their patrons' tentacles and perform guard duty (clownfish are as aggressive as guard dogs in driving off intruders, even though they don't have much of a bark or bite). Researchers agree that anemones tolerate clownfish because they don't recognize the latter's mucus layer (the slimy layer covering the outer surface of all fish) as "foreign." But how do clownfish disguise themselves?

On this, there is no agreement. Schlichter, a German scientist, thinks clownfish coat themselves with the anemone's own mucus by rubbing up against anemones during an "acclimation period." Lubbock, an Englishman, thinks clownfish mucus may be "inert," meaning that without any change at all it would trigger no response from anemones. But Dick Mariscal, who works out of Florida State University, thinks clownfish manufacture *new* mucus (the right stuff) during acclimation.

To prove it, Mariscal and Randy Brooks (now of Auburn University) cut rubber bands into one-inch strips, then glued them to the base of a petri dish until they had created something resembling an anemone. They put some *Amphiprion clarkii* into a tank with the dummy, left them there several days, and then transferred them into another tank with a real anemone. They wanted to see if the experiment affected acclimation time, the time it takes before a clownfish no longer gets stung. As Brooks and Mariscal later reported, "the average acclimation time to a real anemone was 156.9 minutes, compared with 21.7 minutes for those fish previously allowed to orient to the surrogate."

What had happened to the fish that lived among the rubber bands? They certainly hadn't picked up any anemone mucus (Schlichter), and if their mucus was inert (Lubbock), living with the fake wouldn't have changed anything. Mariscal and Brooks believe the experimental clownfish may have adjusted faster because they had already gone through most of the basic biochemical change that enables them to cohabit with anemones.

Photographer Jeff Rotman has no opinion on such slimy matters. He knows only that clownfish are best photographed near sundown, when they are settling in for the night. It was near that hour when he waded into the Red Sea in a wetsuit to get this shot.—*D.W.*

Additional Reading

Maya (p. 42)

There are quite a few good books ab the Maya, and many are geared to a academic audience. For example, *Mysterious Maya,* by George E. St and Gene E. Stuart (Washington, D National Geographic Society, 1977), i up-to-date account of Maya civiliza enhanced by many fine pictures. Pat Culbert's *The Lost Civilization* (N York: Harper and Row, 1974) prov concise coverage of the Classic per while Charles Gallenkamp's *Maya* (N York: Penguin Books, 1981) covers whole of the civilization. Norman H mond's *Ancient Maya Civilization* (N Brunswick: Rutgers University Pr 1982) explores the empire's flowe and fall, its social structure, politics, art. According to John S. Henderson, *World of the Ancient Maya* (Ithaca: nell University Press, 1981) is "a surve the Maya cultural tradition: an introd tion to the societies that make it up an exploration of their contrasts, connecti and linked historical development."

Audubon (pp. 88, 94)

Alexander B. Adams's *John James dubon* (New York: G.P. Putnam's S 1966) is a well-researched biography the famed artist-naturalist. John Chan lor, a British antiquarian book dealer, wrote a popular biography of Audu (see *Audubon,* New York: Viking Pr 1978), made special, in part, because had access to materials in Europe aren't usually seen by the public. A Elizabeth Ford edited *The Bird Biog phies of John James Audubon* (N York: Macmillan, 1957), in which wrote about his subjects. F.H. Herri *Audubon the Naturalist,* the first m study of Audubon, was reprinted by ver in 1968. Dover also reprinted, in 19 Maria R. Audubon's version of her gra father's diaries, *Audubon and His Jo nals.* Using Audubon's writings as t guide, Mary Durant and Michael H wood—both talented writers—set ou retrace his journeys across America. T describe their adventures in *On the R With John James Audubon* (New Y Dodd, Mead and Co., 1984).

Rita Cam

From your northern neighbour, two superb asterpieces to celebrate Canada's world-famous parks.

Diam. 1.41 in. (36 mm)
Wt. 23.3 g

Diam. 1.06 in. (27 mm) Wt. 16.965 g
Comp. 91.7% gold 8.3% silver

Splendid scenery. agnificent wildlife. Springs. Caves. Lakes. Mountains. Waterfalls. Forests.

Mother Nature works overtime Canada. That is why some of the rld's most spectacular parks are ated right next door...in Canada.

To celebrate the Centennial of nada's National Parks, the Govern- nt of Canada has authorized the yal Canadian Mint to issue two y special 1985 commemorative ns – the $100 Gold Coin and the of Silver Dollar.

The 1985 $100 Gold Coin

You will treasure this 22-karat proof $100 gold coin, the 10th in a prestigious series. Unlike most gold coins, its precious metal content – one-half troy ounce of pure gold alloyed with pure silver – makes it an heirloom issue of unsurpassed quality.

A magnificent bighorn sheep, meticulously rendered by Toronto artist Hector Greville, graces the reverse. The design is flawlessly executed in a rare combination of frosted and brilliant relief on a lustrous field. The obverse bears Arnold Machin's classic effigy of Queen Elizabeth II.

The $100 gold coin is presented in a deluxe leather case with a numbered Certificate of Authenticity attesting to the coin's legal tender status.

The mintage is strictly limited to a maximum of 200,000 worldwide – or the deadline of December 15, 1985 – whichever comes first.

The 1985 Proof Set.
Also available is the *1985 Proof Set* featuring the Silver Dollar plus the six 1985 circulating coins from the Cent to the Nickel Dollar. This is the only complete set of Canadian coins that are all in frosted relief on a brilliant field. It comes protectively sealed and mounted in a deluxe case.

The 1985 Silver Dollar

You will cherish this 20th coin in an extraordinary series of commemorative silver dollars. And only the 5th to be minted in proof condition.

Composed of 50% pure silver, the coin displays Karel Rohlicek's graphic depiction of a moose wading in a lake. Struck in an elegant combination of frosted relief on a brilliant field, the Silver Dollar is encapsulated and displayed in a black case. The obverse carries Arnold Machin's effigy of Queen Elizabeth II.

Orders for the Silver Dollar and the Proof Set will be accepted until December 15, 1985.

Avoid disappointment. Order today.

Here is the ideal opportunity to start your collection of Canadian coins, add to your present acquisition or introduce your children to the joys of collecting. And, of course, Canada's numismatic coins make fine gifts for any occasion.

Orders for the 1985 Commemorative issues will be accepted until December 15, 1985.

Do not delay. Complete and mail your order today!

The Royal Canadian Mint is the Official Government Mint of Canada.

1985 Order Form: Canadian Coins

$100 Gold Coin (90621)	$260.00 (U.S.)	
Proof Set (90616)	$34.00 (U.S.)

T. Patrick Culbert (page 42) has taken a lively interest in the recent breakthroughs in deciphering Maya hieroglyphs, which may help solve the mysteries of Classic Maya civilization. Culbert's major fieldwork has been at the lowland site of Tikal, in Guatemala. He is currently preparing a monograph detailing all the ceramics recovered there during fourteen years of excavation. He is also researching the ecological and demographic factors involved in the collapse of Maya civilization. After college, Culbert was a chemical researcher, but his interest in archeology led him to graduate studies in anthropology. He is now a professor of anthropology at the University of Arizona.

In studying the development of early American natural history and art, **Phillip D. Thomas** (page 94) considered Audubon's life and continuing popularity a logical focus for investigation. From 1981 to 1984, while living in Alaska, Thomas became interested in the role played by polar naturalists in describing the flora, fauna, and resources of arctic regions. He collects books and prints on the history of exploration and natural history illustration and enjoys building models of ships used by explorers. Other hobbies include such outdoor activities as fly-fishing, backpacking, and kayaking. A professor of history at Wichita State University, Thomas is dean of the university's Fairmount College of Liberal Arts and Sciences.

Kenneth C. Parkes (page 88) pu research in a range of topics, inclu the systematics and distribution of b plumage variations, molting, metho determining the age and sex of live b and hybridization. His fieldwork taken him around the United States to the Philippines, Argentina, and M ico. An admirer of bird art since he w child, Parkes wrote his master's thes color illustration of North Amer birds and has been on a jury for two art shows. He has long been intrigue the possibility that some unident birds depicted by Audubon were brids. In 1953, Parkes joined the sta the Carnegie Museum of Natural tory in Pittsburgh. He is now the m um's curator of birds and chief cur of life sciences.

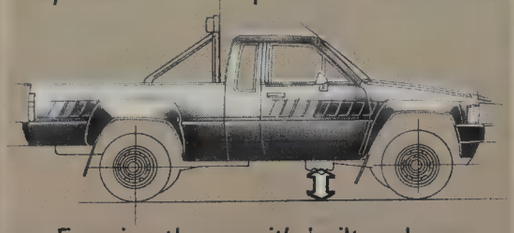
Declare your independence. Bust out. Take off.

And escape to the high country in *OFF ROAD*'s small 4X4 of the year.* It's got the highest running ground clearance in its class. So you can ride high over obstacles—not into them. With solid steel skid plates under the transfer case and fuel tank, you've got two less things to worry about.

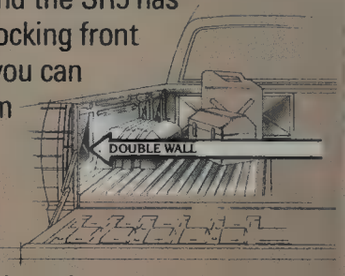
Kick up some dust and leave the pack coughing with the most powerful engine ever built for a truck in its class. Bar none. The 116 powerful horses in its 2.4 liter engine, fed by Electronic Fuel Injection, give it the muscle to do it.

You'll not only run faster, you'll unshackle yourself from most repair bills, too. Ask around. Toyota owners reported the lowest incidence of repairs for any small truck—imported or domestic.**



Examine the way it's built and you can see why. Double wall construction can take the slams of a 1,400-pound payload.*** Its suspension system with solid front-and-rear axles has been proven off-road for reliability and durability. Protected like a tank, this feisty 4X4 boasts wide P225/75R15 tires, and pounds along because it can take a pounding.

To free you from want in the cab, there's full, rich carpeting, and an AM/FM/MPX sound system. The Xtracab includes extra space behind the seats and the SR5 has automatic locking front hubs—so you can change from 2WD to 4WD on command from the comfort of the cab.



Don't be a slave to an ordinary truck. This one's your getaway.

*OFF ROAD, March 1985

Membership/ Subscription Problems?

We Want To Help!

Sometimes, all you need is information. Here are some helpful facts:

Orders – Changes of Address

It takes us from 6 to 8 weeks to process an order, a payment, a renewal, a change of address, or any kind of adjustment to your membership/subscription. So count on about 6 to 8 weeks from the time you place an order until the time you get your first magazine. If you send us a change of address, count on the same 6 to 8 weeks before the magazine is delivered to your new address. (And remember, when registering a change of address, be sure to give us your old address as well as your new one.)

Bills – Renewals

If you send us a payment, you may receive another bill, or even two, before the payment is recorded, and the computer is told to stop sending you bills. Don't be concerned. Just ignore the extra bill. If you send us a renewal, you may receive one or even two more renewal notices before the renewal is recorded, and the computer is told to stop sending you renewal notices. Please respond to only one notice and ignore the extras. And remember, if you wait until just before your membership/ subscription expires to renew, you may miss one or even two issues before the renewal is recorded. Renew early to avoid this possibility!

New Offers

If you are already a member/subscriber, and you receive a new member/subscriber's introductory offer from us, it's because we have used another reputable organization's mailing list. We aren't perfect. We try to screen out our own subscribers' names from these lists to save money, but sometimes it isn't possible. If there is even the slightest difference in the name and/or address (for instance, Mary Roberts and M. Roberts, or Mrs. Roberts, or 12 Oak Road and 12 Oak) the computer can't tell that it's the same name. So we'd appreciate it if you'ld simply give that introductory offer to a friend you think might enjoy Natural History.

Missed Issues

If you miss one or more issues, it may mean that your name and address have been entered incorrectly on our computer, or that we haven't received your payment, or renewal instructions. Or the Postal Service may have failed to deliver the copy that we sent. If you miss one or more issues, please contact us. With your help, we'll rectify whatever mistake was made.

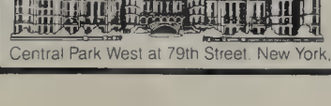
Problem Correspondence

If you have written to us about a problem and not received an answer, please don't be upset. We may have been able to solve the problem without further correspondence. If the problem persists, though, don't hesitate to contact us directly. Remember to give us your complete return address as it appears on your magazine label, or we won't be able to write back.

For help or information on your membership/subscription, write:
Natural History Membership Services
Box 4300
Bergenfield, N.J., 07621
Or call: **212-690-0570**

We're anxious to give you the best possible service. Your co-operation will help us to do that. Thank you!

AMERICAN MUSEUM OF NATURAL HISTORY



Central Park West at 79th Street, New York, N.Y. 10024

own child's performance, parents also comment favorably to other moms and dads whose children have done well. Parents sit in silent embarrassment or make audible excuses when their children don't match or better their former best times.

American children are motivated to keep on swimming because they know that even if they don't achieve a new time in one event that day, they might better their time in another. Because they are allowed to swim in as many events as they have A times (for an A meet) or B times (for a B meet), most swimmers usually have something to be happy about when they get home.

An American swimming meet closely mirrors the larger society in that most people have good and bad moments, strong and weak performances, and despite disappointments, generally find rewards. Swimming is a particularly appropriate sport for a competitive, achievement-oriented society in which lines of social class are not clearly and rigidly drawn. Status within the American swimmer's world is like the form of social organization that anthropologists call the chiefdom, common a century ago in the Polynesian islands. In the chiefdom, slight gradations in prestige and power, rather than demarcated social classes, meant that everyone had a distinctive social status, just a bit higher or lower than anyone else's. A swimmer's unique status is the end result of a complex scoring process that takes into account a series of constantly changing times in different events. Like a Polynesian, every swimmer has a social status slightly different from everyone else's.

Time, then, is the basis of social status in American swimming. Public recognition of excellent times is, in itself, a potent reward. The more tangible prizes—medals and ribbons—go to only a small number of finalists (normally six, eight, or twelve), but everyone has a best time.

Since precious commodities usually have guardians, the swimmer's world has guardians of time (for example, parents armed with the most modern stopwatches). Even when electronic timing pads are used, each lane always has two human timers. There are also finish judges to determine finish order in close races and, for important meets, winning-lane timers. At the end of each heat, times are written on cards, which are used to determine and list finish order, official times, and winners. The results of each race are posted one by one in the halls of the building (usually a high school) where the meet takes place. By consulting these sheets, parents can compare their children's times with previous bests and with those of other swimmers. In this way the adu members of the society monitor wheth their young are keeping up with the peers and whether they are betteri themselves in terms of the values emph sized in American culture, including ind vidual achievement and hard work.

Swimmers' times—these public, pr cious symbols of achievement—a tended, guarded, enshrined in print, a transmitted from local to state to nation levels, where they are used to establi rankings. The most important source of i formation about times and nation rankings is the monthly magazine *Swi ming World*. *Swimming World* also pu lishes results of meets held throughout t

country, and sells a popular T-shirt, pr claiming "I made it in *Swimming World* an achievement that confers considerab prestige among fellow swimmers. The pa ticularly American character of the swi mer's world just described emerges cr tal clear when we consider the same sp in Brazil.

Before enrolling my son in a compe tive swim program in Rio de Janeiro 1983, I accepted the above procedure part of swimming per se—not as an illu tration of distinctive American cultu values. Even though I am accustomed comparing American institutions and b havior with those of other cultures, I h not thought much about how swim pr grams might be run differently elsewhe or what the meets might tell me about d ferent values and traditions. But striki differences between Brazilian and Ame can swimming were soon apparent. Fir Brazilian swim teams are associated w private, money-making professional clu such as the Fluminense Football (socc Club, for which my son swam. Most of t soccer clubs that battle for city, state, a national championships have divisions amateur sports, which manage swimmi gymnastics, and other competitive pr grams for children.

The clubs are commercial organiz tions, rather than the high school, colle age-group, and sports-club teams th dominate competitive swimming in t United States. It was as though my s were swimming for the Detroit Tige

Northwest Orient's Alaska: Nonstop or direct every day from every corner of the U.S.A.

Going to Alaska this summer? Beginning June 6, Northwest Orient will make the going easier . . . with more nonstops and more direct flights from more of America.

■ Daily nonstops from Minneapolis/St. Paul and Seattle/Tacoma.

■ Daily direct flights from the West Coast (Los Angeles, San Diego and Portland); from the Midwest (Chicago); from the Northeast (New York City and Boston); and the Southeast (Tampa/St. Petersburg and Miami).

■ Plus convenient connecting service from other cities coast to coast and border to border.

If you're planning an Alaska trip before June 6, you'll find our spring schedule (4/28 to 6/6) very accommodating too.

Enroute, you'll enjoy meals with the hearty flavor of Alaska—such as Alaskan salmon, reindeer sausage or crab omelets. There's complimentary Yukon Jack for Klondike Coffee and Midnight Sunrises.

For information and reservations, call your travel agent.

Or call Northwest Orient toll-free at (800) 225-2525.

NORTHWEST ORIENT

The world is going our way.

One of the tasks of the vice-president for amateur sports of a Brazilian club is to find rich sponsors, businesses or individuals, national or foreign, for the swim team. The soccer rivalry between such teams as Fluminense, Flamengo, and Vasco spills over into amateur sports. In Rio de Janeiro, swimmers and gymnasts play their own small parts in an ongoing battle for sports supremacy, and the system is similar in other Brazilian cities.

Daily practices are held in the Olympic-sized pools of the different clubs, and the competition is stiffer in a city of eight million than in the Detroit metropolitan area. Many Brazilian national champion age-group swimmers live in Rio, and their times (at least through the early teens) are comparable to those of top American swimmers. Cutoffs are much more stringent, however, and there are fewer meets—which means that swimmers lack opportunities to better their times and to gain experience.

Compared with the United States, Brazilian meets are badly organized. In the United States, meets are planned a year in advance; in Brazil, coaches often don't know until a day or two before the meet where it will be held, and sites are frequently changed at the last minute—for example, from a convenient pool a few blocks away to a suburb requiring an hour's drive. Cariocas (residents of Rio de Janeiro) are accustomed to associating with family and friends, but not with such strangers as the parents of their children's colleagues. There is no tradition of car pooling, and swimmers frequently miss meets because of last-minute changes. For American swimmers, to miss a meet is practically unheard of; mild illnesses or relatives' birthday parties are not acceptable excuses for letting down one's teammates. If one is scheduled to swim a relay, to miss a meet is considered especially unfair to other team members.

American swim meets almost always have relays—freestyle and medley (backstroke, breast stroke, butterfly, and freestyle, or crawl). Brazilian meets, however, rarely include relays; only one of the half dozen meets I attended in Rio had them. Perhaps relays are almost always a part of American meets because they embody key American values so well. The free relay is based on pure speed; it is the fastest of the races because everyone swims the fastest stroke, the crawl, normally called "the free."

The medley relay tests speed through specialization; each of four specialized swimmers tries for a best time to bring his or her team in first. It shows specialized individuals working rapidly together, like an efficient industrial or managerial team. Making the relay through a best time is a valued achievement. In relays, the win is more important than in individual events. Since relay members can change from week to week, swimmers have a less accurate recollection of relay times than personal ones. In these events, swimming celebrates certain American values: winning organization, competition through speed, efficiency, and specialization with other, similar groups. These values have spread out from the American economy to the larger society and are well represented in competitive swimming. In Brazil, the absence of relays helps focus attention on the individual win.

Even more noteworthy, however, than capricious meet planning and the absence of relays is the treatment of time in Brazilian swimming. In the United States, times are recorded electronically, as well as by people with stopwatches, and are publicly posted. In Brazil, however, times are not published in the mimeographed meet program. The swimmers' names and club affiliations are listed for each event, but their times are not. At first I supposed that, as in the United States, names were listed in an order established by prior best times and that the fastest swimmers swam in the last heat. After observing the results of several races in different meets, I learned this was not the case. Swimmers in the first or second heat were as likely to win as those in the last one.

Since times are not listed, parents and swimmers can concentrate only on who wins, not on who betters former times, which means that, rather than several possible winners, each event has only one. Public recognition of improvement—a key reward and powerful reason to keep on swimming—is missing. Nor are times publicly posted after each race. They are announced by loudspeaker after finish order is determined, beginning with the slowest swimmer and laboriously moving up to the winner—sometimes through twenty or thirty names. In this way parents and swimmers are reminded, not that many swimmers have improved, but that there are twenty times as many losers as winners.

Another feature of the Brazilian meet illustrates different cultural values about time. Where were the many guardians of time? I saw no attentive parents with stopwatches; there were no frantic winning-lane timers. Each lane had a single timer—even when the electronic pads weren't working. And, since timers often chatted as swimmers raced home, times were occasionally lost, an unheard-of occurrence in USS swimming. Times are not gathered, tended, and cherished as in t United States. This is one of many sy bolic statements in the swimmer's wo of the different values attached to time the cultures of the two Western giants.

Brazilian coaches do keep track of th swimmers' times, which they use to det mine who will swim what events in t next meet. But in contrast to USS swi ming, in which kids are normally enter in all races for which they have made c off times, in Brazil they are limited three of four races. This further reduc their opportunities for meet experience

Why are there so few opportunities swim competitively in Brazil? One reas is the absence of public school, partic larly high school, athletic programs. A other is the reduced level of parental volvement in organizing and runni meets, compared with that in the Unit States. There are simply too few volu teers to provide the needed chances compete, particularly in a city of eig million where thousands of young peo train as swimmers.

The pattern of stiff cutoffs and stricted competition is persistent and h unfortunate consequences for Brazil in ternational competition. For example, t Brazilian Olympic Committee did n send female swimmers to Los Angeles 1984 because none had made arbitrar established cutoffs. This excluded a Sou American record holder, while swimm with no better times were attending t Olympics as representatives of oth South American countries. The attitu was that only swimmers who had ma the cutoffs had any chance to place in L Angeles. No one imagined that the pov of Olympic excitement might spur swi mers to extraordinary efforts. During te vision coverage of the 1984 South Ame can Championships, held in Rio, I w aghast to hear commentators downgra chances that any Brazilian other than cardo Prado might win a medal. M than once I heard this comment abou new champion: "He doesn't have a char to win at Los Angeles because his ti isn't good enough"—as though it cou never get better.

American coverage, in contrast, do on unexpected results, showing adheren to an American sports credo: "It's not o till it's over." In Brazil, the credo seems be "It's over before it's begun."

Winning, of course, is an import American cultural value, and this is p ticularly true for college and professio team sports like football, basketball, a baseball. Football coaches are fond making such comments as "Winning is a good thing; it's the only thing" a

Buy a Nikon FG and get something you're already an expert at using.

Everything about the Programmed Nikon FG is easy to use.

First, when you buy an FG camera and lens between March 1 and June 30, you get a $25 rebate.* And chances are, you know exactly how to use that.

But the FG offers you much more than a rebate. With three modes, Programmed, Automatic and Manual, it offers you as much, or as little automation as you want.

There's even Through-The-Lens flash metering (TTL), which makes even the most complex flash pictures easy to take.

And if you check the indicated space on the rebate application, you'll get a free FG Instruction Videotape, which will teach you everything from how to load the camera to how to light and compose great pictures.

What's more, you'll automatically become a member of the Nikon USA Club when you return the FG warranty application. As a member, you're entitled to special offers and promotions on additional Nikon equipment.

The USA Club presents the Nikon FG Instruction Videotape.

So consider the Programmed Nikon FG. You'll get a camera you can spend years with.

And something you can spend in a minute.

Nikon®

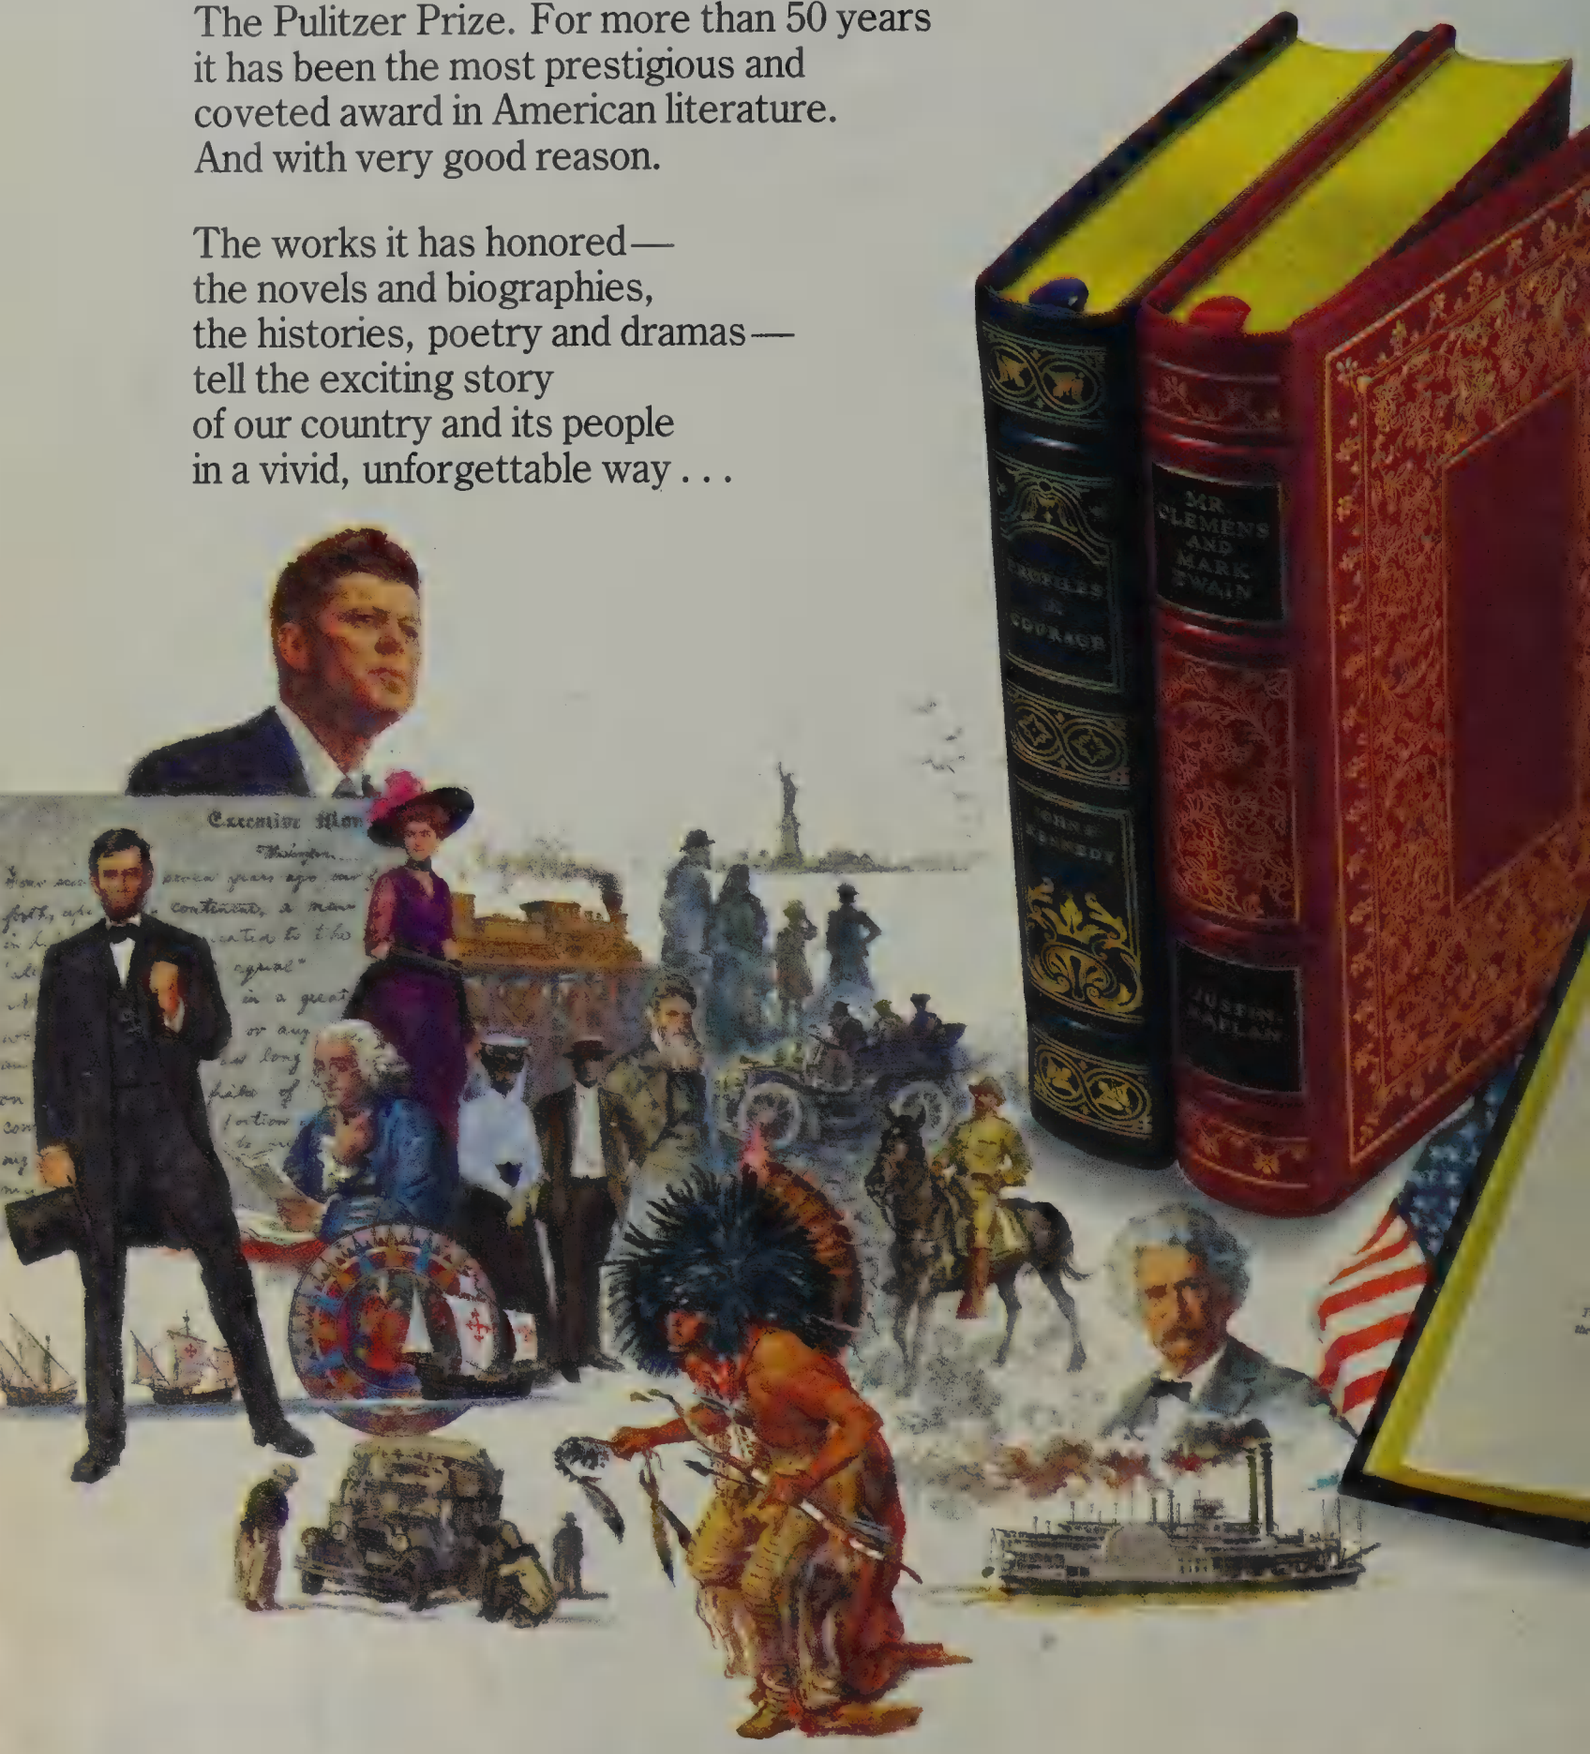
We take the world's greatest pictures.®

Offer applies only to eligible Nikon Inc. USA products. For further information, write Dept. 47, Nikon Inc., 623 Stewart Ave., Garden City, NY 11530 © Nikon Inc. 1985.

America's best.

The Pulitzer Prize. For more than 50 years it has been the most prestigious and coveted award in American literature. And with very good reason.

The works it has honored—
the novels and biographies,
the histories, poetry and dramas—
tell the exciting story
of our country and its people
in a vivid, unforgettable way . . .



The Franklin Library of Pulitz

The Pulitzer Prize. America's most important literary award for over half a century.

Congratulations you giants of American literature.

ake a bow Ernest Hemingway and James chener. Stephen Vincent Benét. Robert nn Warren and Carl Sandburg. Sinclair wis, Thornton Wilder and Tennessee illiams. Bellow, Van Doren, Catton and ost. Wharton, Steinbeck, Pearl Buck and arianne Moore. Barbara Tuchman . . . illiam Faulkner . . . John Updike . . . John ersey . . . Theodore White.

The list of Pulitzer Prize winners is a roll ll of the greatest American writers of r century.

Each of you stands tall among the giants. You had what it took and you did it—and ch of you bought a piece of the rainbow posterity.

So here's to you, judges of the Pulitzer ize Board. For it was you who recog-zed their talent, their greatness, their nius. And who awarded their literary asterworks the honor so deserved. In the aring of your conscience, you confirmed e importance of their achievements. In ices as sensible and sensitive as the quiet ning of your own considered judgment. ithout crowds on Times Square or a lot of evision hoopla.

Now its your turn, lovers of great lit-ature—young and old alike—who also mire the accomplishments of these gi-ts of American literature. And who want preserve them. To be read, enjoyed and admired. To be appreciated today, and later passed on to children and grandchildren. A living legacy to future generations.

That is why the world's leading publisher of great books in fine bindings is now creating the definitive collection of Pulitzer Prize-winning books. The most outstanding novels, plays, biographies, poetry and historical narratives ever chosen for that most coveted of awards—all in one collection.

A sumptuous fifty-volume private library. Each book fully bound in rich, genuine leather. Embellished with 22 karat gold. Magnificent illustrations. Handsome marbled endleaves. Gilded page edges. Even bookpapers milled to last for hundreds of years.

It is a collection like no other. Built of literary landmarks that reflect the heritage of our nation and its people—and that have won for American literature the admiration and respect of the entire world.

The works speak for themselves:

Towering novels—Hemingway's *The Old Man and the Sea.* Robert Penn Warren's *All the King's Men.* Great plays like *Our Town* and *A Streetcar Named Desire.* Marvelous poetry by Robert Frost, Carl Sandburg and Stephen Vincent Benét. Notable biographies—Charles Lindbergh's *The Spirit of St. Louis, Eleanor and Franklin* by Joseph P. Lash. And powerful historical narratives—*A Stillness at Appomattox* and *The Guns of August.*

Here is a collection that will truly bridge the decades. That will bring together, for the first time, the finest works that have won America's highest literary award.

Each volume stands on its own. And each was individually selected by a specially convened panel of prominent Americans: Harrison E. Salisbury, editor and foreign correspondent for the *New York Times.* José Ferrer, Academy Award-winning actor. Kenneth McCormick, one of the leading editors in America today. Distinguished playwright Jean Kerr. Carlos Baker, widely admired author and Professor of Literature Emeritus at Princeton University. Clive Barnes, acclaimed drama, dance and arts critic. And Howard K. Smith, TV commentator and winner of every award for excellence in broadcast reporting.

"These are the Pulitzer Prize-winning books," says Howard K. Smith, "that we believe will be as important a hundred years from now as they are today."

We quite agree. Or we wouldn't be doing what we're doing.

The collection will be sent to you at the convenient rate of one volume each month. The price is just $29.50 per book. And you will always have the right to discontinue your subscription, simply by giving us thirty days' written notice.

To begin your private library of great American literature, send no money. Just return your application by April 30, 1985.

The happy twinge of satisfaction you feel at this moment is just the beginning.

The Franklin Library of Pulitzer Prize Classics is not associated with or sponsored by Columbia University, which administers the Pulitzer Prizes, or with the Pulitzer Prize Board.

"Show me a good loser and I'll show you a loser." For sports such as running and swimming, however, in which the focus is on the individual, American culture also recognizes and admires moral victories, personal bests, comeback athletes, and special Olympics, and commends those who run good races without finishing first. In amateur sports, personal improvement can be as important as winning.

Americans have been told so many times that their culture overemphasizes winning that they may find it hard to believe that Brazilians seem to value winning even more. Prior to the 1984 Summer Olympics, swimmer Ricardo Prado (instead of the eventual Brazilian gold medalist, Joaquim Cruz) was touted by the media as Brazil's most likely gold medal winner (he was a silver medalist). Prado had won 200- and 400-meter individual medley (IM) events in the 1983 Pan American Games and, until 1984, held the world record for the 400 IM. Commenting on his massive press coverage, Prado observed that only winning athletes were noticed in Brazil—only number ones, never number twos. He blasted the press for formerly neglecting his achievements and those of other Brazilian swimmers who were not, or not yet, world record holders.

Perhaps Brazilians value winning
much because it is so rare. In USS swi
ming, the focus on times means there a
always multiple winners. This may be t
key to the relationship of swimming to cu
tural values. In American society, whe
poverty is less pervasive, resources mo
abundant, social classes less marke
opportunities for achievement more n
merous, and individual social mobili
easier than in Brazil, there can be multip
winners. Brazilian society is more stra
fied; a much smaller middle class and eli
group makes up at most 30 percent of t
population. Brazilian swimming echo
lessons from the larger society: victori
are scarce and reserved for the few.

But there is another dimension to t
relationship between competitive swi
ming and society. Even in the Unit
States the opportunity to swim compe
tively is limited, generally to people of t
middle class and above. To swim serious
in America requires money, time, and p
rental involvement. American childr
begin swimming competitively for spo
clubs or country clubs, which have me
bership fees. Success in summer swi
ming may then lead them to join Y or US
programs, for winter competition. T
United States is an automobile-orient
culture. Cars and parents' time are nec
sary to drive to practices and meets. Du
ing Michigan winters, in order to arrive
distant meets for 8:00 A.M. warmups, m
son and I have sometimes spent the nig
in a motel. Swimmers' parents ha
money to spend on gas, food, lodging, a
club memberships. Children whose p
ents can afford to belong to clubs are mo
likely to get interested in swimming in t
first place.

In Brazil the situation is somewhat d
ferent. Public transportation is better
Brazilian cities than in most parts of t
United States. There is less resident
segregation of rich and poor, black a
white. Given the dense urban populatio
and that the major soccer clubs—a
therefore their swimming pools—are
cated right in the city, poor kids, includi
black children, can work out as swi
team members almost as easily as childr
from middle-class families. As a result,
contrast to the United States, where it
rare to see a black swimmer at a US
meet or in a state championship, swi
mers with dark skins and fast times a
present at virtually any carioca swimmi
meet.

Some Americans think that blacks a
whites excel in particular sports becau
of biological and physiological diff
ences, but Brazil, which has proportio
ately as many blacks as the United Stat

Zeiss.

monstrates that sports abilities reflect lture rather than biology. When blacks ve opportunities to do well in swimming, soccer, or tennis, they are physically pable of doing as well as whites. In hools, parks, and city playgrounds in the nited States, blacks have access to basell diamonds, basketball courts, football lds, and tracks. However, because of restricted economic opportunities, black milies have traditionally lacked the resurces to invest in hockey or ski equipent or join clubs with tennis courts and vimming pools. But as Brazilian swimming demonstrates, when these opportunties are available, blacks do well.

Here then is a different way in which e swimmer's world provides a microsm of the surrounding culture. Despite e emphasis in the United States on the ssibility of rising through hard work and dividual achievement, in swimming, as society, success is easiest for those who e better off to begin with.

What can we conclude about the differt cultural models for competitive swimming? Perhaps the more relaxed approach swimming encountered in Brazil rects a culture in which there is less emasis on time, measurement, comparin, and achievement. Brazilians may en experience fewer stresses and be happer because they live in a less competive, less achievement-oriented society. Whatever the case, one thing is eminently ear: the United States is a better training ound than Brazil for international comtitive swimming. As we know from ars of Olympic games and a glance at day's world records, the countries that best at swimming are the United ates, East Germany, and the Soviet nion. State support of Soviet and East erman swimmers is a powerful incentive r talented young people in those counes. Other nations that do well in internaonal competition—Australia, Canada, reat Britain, the Netherlands—are ore like the United States than Brazil in eir cultural backgrounds and current soeconomic conditions.

Despite pride in country, Brazilian vimmers know that it wasn't accidental at the South American giant could mange only one medal while its North Ameri n counterpart was winning thirty-four. ecognizing this, most of the Brazilian en who swam in the 1984 Olympics, inuding silver-medalist Ricardo Prado, are w training in the United States.

Red Wings in the Sunset

Scientists, and artists, can be led painfully astray by the single-minded pursuit of an idea

by Stephen Jay Gould

Teddy Roosevelt borrowed an African proverb to construct his motto: Speak softly, but carry a big stick. In 1912, a critic turned Roosevelt's phrase against him, castigating the old Roughrider for trying to demolish an opponent by rhetoric alone: "Ridicule is a powerful weapon and the temptation to use it unsparingly is a strong one. . . . Even if we don't agree with him [Roosevelt's opponent], it is not necessary either to cut him into little pieces or to break every bone in his body with the 'big stick.' "

This criticism appeared in the midst of Roosevelt's presidential campaign (when he split the Republican party by trying to wrest the nomination from William Howard Taft, then formed his own Progressive, or Bull Moose, party to contest the election, thereby scattering the Republican vote and bringing victory to Democrat Woodrow Wilson). Surely, therefore, it must record one of Roosevelt's innumerable squabbles during a tough political year. It does not. Francis H. Allen published these words in an ornithological journal, *The Auk*. He was writing about flamingos.

When, as a cynical and posturing teenager, I visited Mount Rushmore, I gazed with some approval at the giant busts of Washington, Jefferson, and Lincoln, and then asked as so many others have—what in hell is Teddy Roosevelt doing up there? Never again shall I question his inclusion, for I have just discovered something sufficiently remarkable to warrant a sixty-foot stone likeness all by itself. In 1911, an ex-president of the United States, after seven exhausting years in office, and in the throes of preparing his political comeback, found time to write and publish a technical scientific article, more than one hundred pages long: "Revealing and Concealing Coloration in Birds and Mammals." (As a parochial note of some interest, Roosevelt published his work in the *Bulletin of the American Museum of Natural History,* our professional journal still vigorously in print.)

Roosevelt wrote his article to demolish a theory proposed by the artist-naturalist Abbott H. Thayer (and defended by Mr. Allen, who castigated Roosevelt for bringing the rough language of politics into a scientific debate). In 1896 Thayer, as I shall document in a moment, correctly elucidated the important principle of countershading (a common adaptation that confers near invisibility upon predators or prey). But he then followed a common path to perdition by slowly extending his valid theory to a doctrine of exclusivity. By 1909, Thayer was claiming that *all* animal colors, from the peacock's tail to the baboon's rump, worked primarily for concealment. As a backbreaking straw that sealed his fate and inspired Roosevelt's wrath, Thayer actually argued that natural selection made flamingos red, all the better to mimic the sunset. In the book that will stand forever as a monument to folly, to cockeyed genius, and to inspiration gone askew, Thayer stated in 1909 (in *Concealing-Coloration in the Animal Kingdom,* written largely by his son Gerald H. Thayer and published by MacMillan):

> These traditionally "showy" birds are, at their most critical moments, perfectly "obliterated" by their coloration. Conspicuous in most cases, when looked at from above, as man is apt to see them, they are wonderfully fitted for "vanishment" against the flushed, rich-colored skies of early morning and evening.

Roosevelt responded with characteristic vigor in his 1911 article:

> Among all the wild absurdities to which Mr. Thayer has committed himself, prob
> bly the wildest is his theory that flaming
> are concealingly colored because their fo
> mistake them for sunsets. He has nev
> studied flamingos in their haunts, he kno
> nothing personally of their habits or the
> enemies or their ways of avoiding their en
> mies . . . and certainly has never read an
> thing to justify his suppositions; these su
> positions represent nothing but pu
> guesswork, and even to call them guesswo
> is a little over-conservative, for they con
> nearer to the obscure mental process
> which are responsible for dreams.

Roosevelt's critique (and many othe
equally trenchant) sealed poor Thaye
fate. In 1896, Thayer had begun his ca
paign with praise, promise, and panac
(his outdoor demonstrations of disappea
ing decoys became legendary). He fac
the dawn of World War I in despair a
dejection (though the war itself grant
him limited vindication by using his val
ideas in theories of camouflage). He
mented to a friend that his avocation (c
fending his theory of concealing colo
ation) had sapped his career:

> Never . . . have I felt less a painter . . . I a
> like a man to whom is born, willy nilly,
> child whose growth demanded his energi
> he the while always dreaming that th
> growing offspring would soon go forth
> seek his fortune and leave him to his prof
> sion, but the offspring again and again
> ther unfolding some new faculties th
> must be nurtured and watched, or comi
> home and bursting into his parent's stud
> bleeding and bruised by an insulted wor
> continued to need attention so that the
> was nothing for it but to lay down the bru
> and take him once more into one's lap.

I must end this preface to my essay wi
a confession. I have known about Thaye
"crazy" flamingo theory all my prof
sional life—and for a particular reason.
is the standard example, always used

The day he left the village of his childhood for America.

His family gathered around him on that chilly ovember morning to bid him final farewell. Papa put up brave facade.

He sensed his brother's awkwardness when they nbraced. And, most clearly, he felt a pang of sadness as he oked for one last time into Mama's tearful eyes.

Then the approaching train's high-pitched shriek broke e silence. And his family was suddenly left far behind.

professors in introductory courses to illustrate illogic and unreason, and dismissed in a sentence with the ultimate weapon of intellectual nastiness—ridicule that forecloses understanding. When I planned my flamingo trilogy (this is the last, I promise), I decided to end—how else?—with red wings in the sunset. I thought that I would write a column about absurdity, another comment on unthinking adaptationism. But my research unleashed a cascade of discovery, leading me to Roosevelt and, more importantly, to the real Abbott Thayer, shorn of his symbolic burden. The flamingo theory is, of course, absurd—that will not change. But how and why did Thayer get there from an excellent start that the standard dismissive anecdote, Thayer's unfortunate historical legacy, never acknowledges? The full story, if we try to understand Abbott Thayer aright, contains lessons that will more than compensate for laughter lost.

Who was Abbott Handerson Thayer anyway? I had always assumed, from the name alone, that he was an eccentric Yankee who used wealth and social position to gain a hearing for his absurd ideas. I could find nothing about him in the several scientific books that cite the flamingo story. I was about to give up when I located his name in the *Encyclopædia Britannica*. I found, to my astonishment, that Abbott Thayer was one of the most famous painters of late nineteenth-century America (and an old Yankee to be sure, but not of the wealthy line of Thayers—see the biography by Nelson G. White, *Abbott H. Thayer: Painter and Naturalist*. Connecticut Printers, 1951). He specialized in ethereal women, crowned with suggestions of halos and accompanied by quintessentially innocent children. Art and science are both beset by fleeting tastes that wear poorly—far be it for me to judge. I had begun to uncover a human drama under the old pedagogical caricature.

But let us begin, as they say, at the beginning. Standard accounts of the adaptive value of animal colors use three categories to classify nature's useful patterns (no one has substantially improved upon the fine classic by Hugh B. Cott, *Adaptive Coloration in Animals*. London, Methuen, 1940). According to Cott, adaptive colors and patterns may serve as (1) concealment (to shield an animal from predators or to hide the predator in nature's never-ending game); (2) advertisement, to scare potential predators (as in the prominent false eyespots of so many insects), to maintain territory or social position, or to announce sexual receptivity (as in baboon rump patches); and (3) disguise, as animals mimic unpalatable creatures to gain

White (top) and red (bottom) flamingos against the skies at sunrise and sunset.

protection, or resemble an inanimate (and inedible) object (numerous leaf and stick insects, or a bittern, motionless and gazing skyward, lost amidst the reeds). Since disguise lies closer to advertisement than to concealment (a disguised animal does not try to look inconspicuous, but merely like something else), we can immediately appreciate Abbott Thayer's difficulty. He wanted to reduce all three categories to the single purpose of concealment—but fully two-thirds of all color patterns, in conventional accounts, serve the opposite function of increased visibility.

Abbott Thayer, a native of Boston, began his artistic career in the maelstrom of New York City but eventually retreated to a hermitlike existence in rural New Hampshire, where his old interests in natural history revived and deepened. As a committed Darwinian, he believed that all form and pattern must serve some crucial purpose in the unremitting struggle for existence. He also felt that, as a painter, he could interpret the colors of animals in ways and terms unknown to scientists. In 1896, Thayer published his first, landmark article in *The Auk:* "The Law Which Underlies Protective Coloration" (vol. 13, pp. 124–29).

Of course, naturalists had recognized for centuries that many animals blend into their background and become virtually invisible—but scientists had not properly recognized how and why. They tended to think, naively (as I confess I did before r research for this column), that protecti emerged from simple matching betwe animal and background. But Thayer c rectly identified the primary method concealment as countershading—a devi that makes creatures look flat. Anim must indeed share the right color and p tern with their background, but th ghostly disappearance records a loss of mensionality, not just a matching of col

In countershading, an animal's col are precisely graded to counteract the fects of sunlight and shadow. Count shaded animals are darkest on top, whe most sunlight falls, and lightest on the b tom (Thayer identified the adaptive s nificance of light bellies—perhaps t most universal feature of animal col ation). The precise reversal between int sity of coloration and intensity of illumi tion neatly cancels out all shadow a produces a uniform color from top to b tom. As a result, the animal becomes fl perfectly two dimensional, and cannot seen by observers who have, all their liv perceived the substantiality of objects shadow and shading. Artists have stru gled for centuries to produce the illusi of depth and roundness on a flat canv nature has simply done the opposite—s shades in reverse in order to produce an lusion of flatness in a three-dimensio world.

Contrasting his novel principle

A proving ground for computers.

Nobody makes more automotive computers than General Motors.

No other automotive company subjects their computers to more torture tests. 40 degrees below zero to 185 above. Electron microscope scanning. Moisture. Vibration. Testing that equals 10 years of typical driving.

Our computerization gives you improved driveability. Smooth performance regardless of speed. An indoor climate control system. And greater fuel economy.

And the reliability of our computers makes the operation of your new GM car or truck safer and more efficient.

We believe in taking the extra time, giving the extra effort and paying attention to every detail. That's what it takes to provide the quality that leads more people to buy GM cars and trucks than any other kind.

That's the GM commitment to excellence.

Sculptures of the World's Great Crystal Houses

Twelve Original and Distinctive Crystal Sculptures — Each Produced by One of the World's Most Famous Crystal Houses Exclusively *for this Collection.*

You can now own what traditionally has been the most sought after form of crystal art objects — beautiful museum quality sculptures, issued in an exclusive edition.

A collection impossible to assemble in any other way.

Imagine owning a collection of sculptures created by twelve of the world's most renowned crystal houses ...Baccarat of France...Nybro of Sweden...Hadeland of Norway...Royal Doulton of England...Noblesse of West Germany.

Now, the Danbury Mint is making it easy and affordable to acquire this "dream collection." Our representatives personally invited the directors of twelve of the world's great crystal houses each to create a special sculpture for this unprecedented international collection. And they accepted with enthusiasm!

Original designs each reflecting the pride of its maker.

Each of the sculptures in this collection is different, distinctive, unique. Thus the sculptures are of various sizes, different shapes, different crafting techniques. Each reflects the pride and traditions of its maker and, in many cases, the heritage of the particular nation involved. Every sculpture is different and every one has been produced especially for the Danbury Mint.

Convenient acquisition plan. Satisfaction guaranteed.

You will be pleased to learn that the original issue price of each sculpture is only $45, which is remarkable when you consider that the world's finest crystal houses are involved.

No payment is needed now. You will receive your sculptures at the convenient rate of one every two months and will be billed for each in two convenient monthly installments of $22.50. As a further convenience, you may have each monthly installment charged to your VISA or MasterCard.

Each crystal sculpture will be crafted to the highest standards of excellence. And each will bear the mark of its maker — attesting to its authenticity and impeccable quality. However, in the unlikely event you receive any piece you are not entirely pleased with, you may return it within 30 days of receipt for a prompt replacement or refund. Naturally, you are free to cancel your subscription at any time.

© DM

To be enjoyed today...
and passed on to future generations.

There has never been a more enjoyable, more convenient way to acquire beautiful sculptures from all twelve of these world-renowned crystal houses. Those who admire your collection will assume that you acquired it over many years, perhaps on journeys abroad. They will marvel, as you will, at its scope, beauty, and diversity. You will be complimented on your choice of fine crystals. The collection will be a prized possession, a source of pleasure and delight for you and your family now...and for generations to come. To begin your collection, return the reservation application today. You will be delighted you did.

Shown above are several of the crystals
in one of the many ways you might display them in your home.

RESERVATION APPLICATION

countershading with older ideas about mimicry, Thayer wrote in his original statement of 1896: "Mimicry makes an animal appear to be some other thing, whereas the newly discovered law makes him cease to appear to exist at all."

Thayer, intoxicated with the joy of discovery, attributed his success to his chosen profession and advanced a strong argument about the dangers of specialization and the particular value of "outsiders" to any field of study. He wrote in 1903: "Nature has evolved actual art on the bodies of animals, and only an artist can read it." And later, in his 1909 book, but now with the defensiveness and pugnacity that marked his retreat:

> The entire matter has been in the hands of the wrong custodians . . . .It properly belongs to the realm of pictorial art, and can be interpreted only by painters. For it deals wholly in optical illusion, and this is the very gist of a painter's life. He is born with a sense of it; and, from his cradle to his grave, his eyes, wherever they turn, are unceasingly at work on it—and his pictures live by it. What wonder, then, if it was for him alone to discover that the very art he practices is at full—beyond the most delicate precision of human powers—on almost all animals.

So far, so good. Thayer's first articles and outdoor demonstrations won praise from scientists. He began with relatively modest claims, arguing that he had elucidated the basis for a major principle of concealment but not denying that other patterns of color displayed quite different selective value. Initially, he accepted the other two traditional categories—revealing coloration and mimicry—though he always argued that concealment would gain a far bigger scope than previously admitted. In his most technical paper, published in the *Transactions of the Entomological Society of London* (1903, pp. 553–56) and introduced favorably by the great English Darwinian E.B. Poulton, Thayer wrote:

> Every possible form of advantageous adaptation must somewhere exist . . . .There must be unpalatability accompanied by warning coloration . . . and equally plain that there must be mimicry.

Indeed, Thayer sought ways to combine ideas of concealment with other categories that he would later deny. He supported, for example, the ingenious speculation of C. Hart Merriam that white rump patches are normally revealing, but that their true value lies in a deer's ability to "erase" the color at moments of danger—a deer "closes down" the patch by lowering its tail over the white blotch and then disappears, invisible, into the forest. In his 1909 book, Thayer explicitly repudiated his former interpretation and argued for pure concealment—the white patch as "sky mimicking" when seen from below.

Thayer's pathway to perdition and ridicule followed a distressingly common route among intellectuals. Countershading for concealment, amidst a host of alternatives, was not enough. Thayer had to have it all. Little by little, plausibly at first, but grading slowly to red wings in the sunset, Thayer laid his battle plans (not an inappropriate metaphor for a father of camouflage). As article succeeded article, Thayer progressively invaded the categories of mimicry and revealing coloration to gain, or so he thought, more cases for concealment. Finally, nothing else remained: *all* patterns of color served to conceal. He wrote in his book: "All patterns and colors whatsoever of all animals that ever prey or are preyed upon are under certain normal circumstances obliterative."

Thayer made his first fateful step in his technical article of 1903. Here, he claimed a second major category of concealing coloration—what he called "ruptive" (we now call them "disruptive") bars, stripes, splotches, and other assorted markings. Disruptive markings make an animal "disappear" by a route different from countershading. They break an animal's coherent outline and make it appear as an insubstantial array of curious and unrelated patches (this principle, more than countershading, became important in military camouflage). A zebra, Thayer argues, does not mimic the reeds in which it hides; rather, the stripes break it up, and predators see no coherent prey at all.

Again, Thayer had proposed a good idea for some, even many, cases (though not for zebras, who rarely venture into fields of reeds). His 1903 article argues primarily that butterflies carry disruptive pictures of flowers and background scenery upon their wings: "The general aspect of each animal's environment," Thayer wrote, "is found painted upon his coat, in such a way as to minimize his visibility, by making the beholder think he sees *through* him."

But, amidst his good suggestions, Thayer had made his first overextended argument. Countershading could scarcely be mistaken for anything else and offered little scope for claiming too much. But the principle of "ruptive" concealment permitted enormous scope for encompassing other patterns that actually serve to reveal or mimic. Color patches and splotches—the classic domain of warning and revealing patterns (consider the peacock's tail)—could, for an overenthusiast like Thayer, become marks of disruptive concealment. Thus, to cite just one example of overstatement, Thayer argued in a 1909 article, adversarily entitled "An Arraignment of the Theories of Mimicry and Warning Colors" (*Popular Science*, December), that white patches on a skunk's head mimic the sky when seen by mice from below:

> Such . . . victims as can see would certainly have much more chance to escape were not what would be a dark-looming predator's head converted, by its white sky-counterfeiting, into a deceptive imitation or mere sky.

Still, by 1903, Thayer was not yet ready to claim concealment for all colors. He admitted one category of obvious conspicuousness: "Only unshiny, bright monochrome is intrinsically a revealing coloration."

Now we can finally understand why Thayer was eventually driven to his absurd argument about flamingos and the sunset. Divorced from the context of Thayer's own personal development, the idea sounds like simple disembodied craziness—as professors always present it for laughs in introductory classes. (Indeed, so far as I know, no one, before this essay, has ever tried to make sense of Thayer's ideas by tracing them chronologically through his papers.) Once Thayer decided to go for broke, and to claim that all color works for concealment, flamingos became his crucial test, his do or die attempt at exclusivity. As a last shackle before the final plunge, Thayer had admitted that stark monochromes—animals painted throughout with one showy color—were "intrinsically revealing." If he could show that such monochromes also served for concealment, then his triumph would be complete. Flamingos occupied the center of his daring, not a curious diversion. He had to find a way to fade bright red into ethereal nothingness. Hence the sunset—his as well as the flamingo's.

So Thayer visited the West Indies, got down on his belly in the sulfurous muds, and looked at flamingos—not comfortably down from above (as he always accused lazy and uncritical zoologists of doing), but from the side as a slithering anaconda or a hungry alligator might. And he saw red wings fading into the sunset—the entire feeding flock became a pink cloud, a "sky-matching costume":

> These birds are largely nocturnal, so that the only sky bright enough to show any color upon them is the more or less rosy and golden one that surrounds them from sunset till dark and from dawn until soon after sun-

HOW TO FEEL ON TOP OF THE WORLD WHILE TRAVELLING AROUND IT.

INTRODUCING THE STOWAWAY™ TRAVEL SERIES FROM BLACK & DECKER.

A coordinated line of travel products designed to take care of all your personal grooming needs. Four compact, lightweight appliances with full-size appliance features.

The ***Turbo Dryer*** *and* ***Folding Handle Turbo Dryer****, each with two heat and air settings and loaded with power. The* ***Heated Curling Brush****, with quick heat-up and unique tangle-free bristle design. And the* ***Travel Iron****, with both steam and dry settings, so it performs as well as a full-size model.*

So remember, while you're seeing the world, the world will be seeing you. Let it see you at your best. With the Stowaway Travel Series. From Black & Decker.

rise. They commonly feed in immense, open lagoons, wading in vast phalanxes, while the entire real sky above them and its reflected duplicate below them constitute either one vast hollow sphere of gold, rose, and salmon, or at least glow, on one side or the other, with these tones. Their whole plumage is a most exquisite duplicate of these scenes . . . .This flamingo, having at his feeding time so nearly only sunrise colors to match, wears, as he does, a wonderful imitation of them.

Thayer had finally gone too far and exasperated even his erstwhile supporters. His exaggerations—particularly his flamingos—now brought down a storm of criticism, including Roosevelt's hundred-page barrage. Critics pointed out that Thayer was wrong in every particular: Flamingos do not concentrate their feeding at dawn and dusk, but are active all day; anacondas and alligators do not inhabit the thin films of saline ponds that flamingos favor; flamingos eat by filtering tiny eyeless animals that cannot enjoy the visual pleasures of sunset.

Most sadly, Thayer's argument even failed in its own terms—and Thayer, who was overenthusiastic to a fault, but neither dishonest nor dishonorable, had to confess. Any object viewed *against* the fading light will appear dark, whatever its actual color. Thayer admitted this explicitly by painting a dark palm tree against the sunset in his infamous and fanciful painting of fading flamingos (reproduced here). Thus, he could only claim that flamingos looked like the sunset in the *opposite* side of the sky: red clouds of sunset in the west, red masses of flamingos in the east. Would any animal be so confused by two "sunsets," with flamingos showing dark against the real McCoy? Thayer admitted in his 1909 book:

Of course a flamingo seen against dawn or evening sky would look dark, like the palm in the lower left-hand figure, no matter what his colors were. The . . . right-hand figures, then, represent the lighted sides of flamingos at morning or evening, and show how closely these tend to reproduce the sky of this time of day; although always, of course, *in the opposite quarter of the heavens* [Thayer was good enough to underline his admission] from the sunset or dawn itself.

As a final, and feeble, parting salvo, Thayer added: "but the rosy hues very commonly suffuse both sides of the sky, so that . . . the flamingos illuminated ruddy color very often has a true 'background' of illuminated ruddy sky."

Teddy Roosevelt was particularly perturbed. As an old big-game hunter, he knew that most of Thayer's "ruptive" patterns did not conceal quarries. How could Thayer have it both ways—how could a lion be concealed in the desert, the zebra amongst the reeds when, in fact, they share the same habitat, often to the zebra's fatal disadvantage? Thus, Roosevelt decided to counterattack and wrote his scientific *magnum opus* during some spare time amidst other chores. He saved his best invective for the poor flamingos. Writing on February 2, 1911, to University of California biologist Charles Kofoid, he stated:

[Thayer's] book shows such a fantastic quality of mind on his part that it is a matter of very real surprise to me that any scientific observer . . . no matter how much credit he may give to Mr. Thayer for certain discoveries and theories, should fail to enter the most emphatic protest against the utter looseness and wildness of his theorizing. Think of being seriously required to consider the theory that flamingos are colored red so that fishes (or oysters for that matter—there is no absurdity of which Mr. Thayer could not be capable) would mistake them for the sunset!

The debate between Roosevelt and Thayer developed into an interesting discussion of scientific methodology, not merely some rhetorical sniping about specifics. To grasp Roosevelt's primarily methodological (and cogent) objections to Thayer's work, consider Thayer's most remarkable painting of all—the frontispiece to his 1909 book, showing a peacock obliterated in the foliage. Here, Thayer argues that every nuance of a peacock's coloration increases his concealment in a particular bit of habitat—the combined effect adding to invisibility. Given the usual interpretation of a peacock's color as revealing, and the gaudy impression that he makes both upon us and, one must assume, the peahen, Thayer's interpretation represents quite a departure from tradition and common sense:

The peacock's splendor is the effect of a marvelous combination of "obliterative" designs, in forest-colors and patterns. . . . All imaginable forest-tones are to be found in this bird's costume; and they

"melt" him into the scene to a degree past all human analysis.

Thayer then positions his bird so precisely that all features blend with surroundings. He paints the blue neck against a gap in the foliage, so that it may mimic "blue sky seen through the leaves." He matches the golden greens and browns of the back to forest tones. He depicts the white cheek patch as a "ruptive" hole that disaggregates the face. He paints the celebrated ocelli (eyespots) of the tail feathers as leaf mimics. He also notes that ocelli are smallest and dimmest near the body, grading to larger and brighter toward the rear end: "They inevitably lead the eye away from the bird, till it finds itself straying amid the foliage beyond the tail's evanescent border." The spread tail, he claims, may impress the peahen, but it "looks also very much like a shrub bearing some kind of fruit or flower." Finally, he argues that the tail's coppery brown color represents perfectly "the bare ground and tree-trunks seen between the leaves."

What a tour de force, but what can we possibly make of it? Who would doubt that some conceivable habitat might conceal almost any animal? Note how precisely the peacock must choose his spot to receive the cryptic benefit that Thayer wishes to confer upon him. In particular, he must always place his shimmering blue neck in a gap amidst the foliage where it will vanish against a clear sky (but what does he do on a cloudy day, or in a bush so dense that no holes exist, as seen from all relevant directions at once?). Peacocks, in any case, live primarily in open fields. Their spreading display is a glory to behold—and the very opposite of invisible.

Thayer, of course, knew all this. He didn't claim (as his critics sometimes charged) that a habitat offering protection by concealment must be the usual, or even a common, haunt of its invisible beneficiary. Thayer simply argued that such protection might be important at critical moments occurring only once or twice in an animal's lifetime—at crucial instants of impending death from a stalking predator.

But how could odd and improbable moments shape such complex and intricate patterns as the innumerable details of a peacock's design? We finally arrive at the key theoretical issue of this debate—the power of natural selection itself. In order to believe that complex designs might be constructed by such rare and momentary benefits as sunsets or particular positions in trees outside an animal's normal habitat, one must have an overarching faith in the power of natural selection. Selection must be so potent that even the rarest c benefits will eventually be engraved int the optimal designs of organisms. Thaye has this faith; Roosevelt, and most biolo gists then and since, did not. Thayer wrot in 1900 (*The Auk,* vol. 17): "Of course, t any one who feels the inevitability of natu ral selection, it is obvious that each orga or structural detail, and likewise eac quality of organic forms, owes its exis tence to the sum of all its uses." Thaye then laid it on the line in stark epitome— patterns of color are built by natural selec tion "pure, simple and omnipotent."

Roosevelt and other acute critics co rectly identified the central flaw i Thayer's science—not in his numerou factual errors, but in his methodolog Thayer found a hiding place for all his an mals but with a method that made his the ory untestable and therefore useless t science. Thayer insisted that he ha proved his point simply by finding *an* spot that rendered an animal invisible. H didn't need to show that the creature usu ally frequented such a place or that the lo cation formed part of its natural habitat a all. For the animal might seek its spot onl in the rarest moments of need. But ho then could we disprove any of Thayer claims? We might work for years to sho that an animal never entered its domain c

TAKE THE MACMILLAN ILLUSTRATED ANIMAL ENCYCLOPEDIA for only **99¢** when you join the Natural Science Book Club

YOU SIMPLY AGREE TO
BUY ONE MORE BOOK AT A HANDSOME DISCOUNT
WITHIN THE NEXT 12 MONTHS.

A $35.00 RETAIL VALUE

This breathtaking 600-page volume gives you the closest look ever at the amazing world of vertebrate animals. Luminous, individual paintings by leading wildlife artists show each of the 2,500 creatures in its natural colors. Biographies detail each animal's common and scientific name, family, range, habitat, and conservation status, and describe its appearance, lifestyle, breeding habits, and physiology. For naturalists — professional or amateur — the *Macmillan Illustrated Animal Encyclopedia* is a work of unique value — at a remarkable price!

The Natural Science Book Club is a unique book club devoted to bringing you exciting, refreshingly different books on all areas of the natural sciences. From the life story of early man to the death of the solar system ... all the wonders of the natural world are revealed to members of the Natural Science Book Club.

MEMBERSHIP BENEFITS • In addition to getting the *Macmillan Illustrated Animal Encyclopedia* for only 99¢ when you join, you keep saving substantially on the books you buy. Also, you will immediately become eligible to participate in our Bonus Book Plan, with savings up to 70% off the publishers' prices. At 3-4 week intervals (16 times per year), you will receive the Natural Science Book Club News, describing the Main Selection and Alternate Selections, together with a dated reply card. If you want the Main Selection, do nothing, and it will be sent to you automatically. If you prefer another selection, or no book at all, simply indicate your choice on the card and return it by the date specified. You will have at least 10 days to decide. If, because of late mail delivery of the News, you should receive a book you do not want, we guarantee return postage.

FEATURES:
- **Oversized volume, 11½" x 9"**
- **600 pages**
- **280 full-color illustrations displaying 2,500 animals**

Natural Science Book Club
Riverside, New Jersey 08075 4-BE8

Please accept my application for trial membership and send me the *Macmillan Illustrated Animal Encyclopedia* (59136), billing me only 99¢, plus shipping and handling. I agree to purchase at least one additional Selection or Alternate over the next 12 months. Savings range up to 30% and occasionally even more. My membership is cancelable at any time after I buy this one book. A shipping and handling charge is added to all shipments.

No-Risk Guarantee: If you are not satisfied — for any reason — you may return the *Macmillan Illustrated Animal Encyclopedia* within 10 days. Your membership will be canceled, and you will owe nothing.

Natural History 5/85

nvisibility, and Thayer would reply: Wait ill tomorrow when urgent need arises. Scientists are trained to avoid such special pleading because it exerts a chilling and stupefying effect upon hypotheses, by rendering them invulnerable to test and potential disproof. Doing is the soul of science and we reject hypotheses that condemn us to impotence.

T. Barbour, former director of Harard's Museum of Comparative Zoology where I now sit composing this piece), and J.C. Phillips emphasized this point in reviewing Thayer's book (*The Auk,* vol. 28, 1911):

Acquiescence in Mr. Thayer's views throws a pall over the entire subject of animal coloration. Investigation is discouraged; and we find jumbled together a great mass of fascinating and extremely complicated data, all simply explained by one dogmatic assertion. For we are asked to believe that an animal is protectively clothed whether he is like his surroundings, or whether he is very unlike them (obliteratively marked) or . . . if he falls between these two classes, there is still plenty of space to receive him.

Teddy Roosevelt addressed the same issue with more vigor in a letter to Thayer on March 19, 1912 (just imagine any presidential candidate taking time out to pursue natural history more than a month after the New Hampshire primary—oh, I know, campaigns were shorter then):

There is in Africa a blue rump baboon. It is also true that the Mediterranean Sea bounds one side of Africa. If you should make a series of experiments tending to show that if the blue rump baboon stood on its head by the Mediterranean you would mix up his rump and the Mediterranean, you might be illustrating something in optics, but you would not be illustrating anything that had any bearing whatsoever on the part played by the coloration of the animal in actual life . . . .My dear Mr. Thayer, if you would face facts, you might really help in elucidating some of the problems before me, but you can do nothing but mischief, and not very much of that, when conducting such experiments . . . .Your experiments are of no more real value than the experiment of putting a raven in a coal scuttle, and then claiming that he is concealed.

Contemporary (and later) accounts of Thayer's debacle rest largely upon a red herring, concealed in more than the sunset, that will not explain his failure and that only reinforces a common and harmful stereotype about the intrinsic differences between intellectual styles. In short, we are told that Abbott Thayer ultimately failed because he possessed an artist's temperament—good for an initial insight perhaps, but with no staying power for the hard (and often dull) work of real science.

Discovery Tour to the Nile

February 9 to March 1, 1986

Discover the world of ancient and modern Egypt on an American Museum 600 mile Nile Cruise. Explore with three lecturers the rich natural and archeological sites of an area which has fascinated visitors for centuries...A carefully planned itinerary (with a special two-day program in London visiting the British Museum with its curator) provides a relaxing and thorough three-week Discovery Tour. All of the major Nile archeological sites as well as the important wildlife regions are discussed and visited with your balanced team of eminent lecturers. Share with Museum staff and friends an unforgettable cruise. For further information including itinerary, map, prices, conditions, etc., write or call American Museum Discovery Tours.

Such charges were often lodged against Thayer, and with undoubted rhetorical effect, but they represent a dangerous use of ad hominem argument with anti-intellectual overtones. Thayer may have laid himself open to such ridicule with a passionate temperament that he made no effort to control in a more formal age. John Jay Chapman, the acerbic essayist, wrote of Thayer (admittedly in a fit of pique when his wife, at his great displeasure, decided to study art in Thayer's studio):

> Thayer by the way, is a hipped egoist who paints three hours, has a headache, walks four hours—holds his own pulse, wants to save his sacred light for the world, cares for nobody, and has fits of dejection during which forty women hold his hand and tell him not to despair—for humanity's sake.

But is such passion the exclusive birthright of artists? I have known many scientists equally insufferable.

Thayer's scientific critics also raised the charge of artistic temperament. Roosevelt wrote, in a statement that might have attracted more attention in our litigious age: Thayer's misstatements "are due to the enthusiasm of a certain type of artistic temperament, an enthusiasm also known to certain types of scientific and business temperaments, and which when it manifests itself in business is sure to bring the owner into trouble as if he were guilty of deliberate misconduct." Barbour and Phillips argued that "Mr. Thayer, in his enthusiasm, has ignored or glossed over with an artistic haze . . . .This method of persuasion, while it does appeal to the public, is—there is no other word—simple charlatanry however unwitting." Barbour and Phillips then defended the cold light of dispassionate science in a bit of self-serving puffery:

> [Our statements] are simply the impressions made upon open-minded observers who have no axe to grind, and who have no reason to take sides on the question, one way or another. They have been written in a friendly spirit, and we hope they will be received in the same way.

Do friendly spirits ever accuse their opponents of "simple charlatanry"?

The charge of artistic temperament may be convenient and effective, especially since it appeals to a common stereotype—but it won't wash. The facile interpretation that scientists wouldn't give Thayer a hearing because he was an "outsider" won't work either—for contemporary accounts belie such charges of territoriality and narrowness. Even though Thayer made such strong claims—quoted above—for scientists' incompetence in a domain accessible only to artists, naturalists welcomed his insights about countershading and enjoyed both his initial articles and his outdoor demonstrations. E.B. Poulton, one of England's greatest evolutionists, warmly supported Thayer and wrote introductions to his publications. Frank M. Chapman, great ornithologist and editor of *The Auk,* wrote in his *Autobiography of a Bird Lover:*

> As an editor, doubtless my most notable contributions to the Auk's pages were Abbott Thayer's classical papers on protective coloration . . . .I knew little of Thayer's eminence as an artist. It was the man himself who impressed me by the overwhelming force of his personality. He made direct and inescapable demands on one's attention. He was intensely vital and lived normally at heights which I reached only occasionally and then only for short periods.

Thayer's ultimate failure reflects a more universal tendency, distributed without reference to profession among all kinds of people. Nothing but habit and tradition separate the "two cultures" of humanities and science. The processes of thought and modes of reason are similar—so are the people. Only subject matter differs. Science may usually treat the world's empirical information; art may thrive on aesthetic judgment. But scientists also traffic in ideas and opinions, and artists surely respect fact.

The *idée fixe* is a common intellectual fault of all professions, not a characteristic failure of artists. I have often written about scientists as single-mindedly committed to absurd unities and false simplifications as Thayer was devoted to concealing coloration as an exclusive principle in nature. Some are charming and a bit dotty—as old Randolph Kirkpatrick, who thought that all rocks were made of single-celled nummulospheres (see my column of March 1978). Others are devious and more than a bit dangerous—as Cyril Burt who fabricated data to prove that all intelligence resided in heredity (see my book *The Mismeasure of Man*).

Abbott Thayer had an *idée fixe;* he burned with desire to reduce a messy and complex world to one beautiful, simple principle of explanation. It doesn't work. History has built irreducible complexity and variety into the bounteous world of organisms. Diversity reigns at the superficial level of overt phenomena—animal colors do many different things. The unifying principles are deeper and more abstract—may I suggest evolution itself for starters.

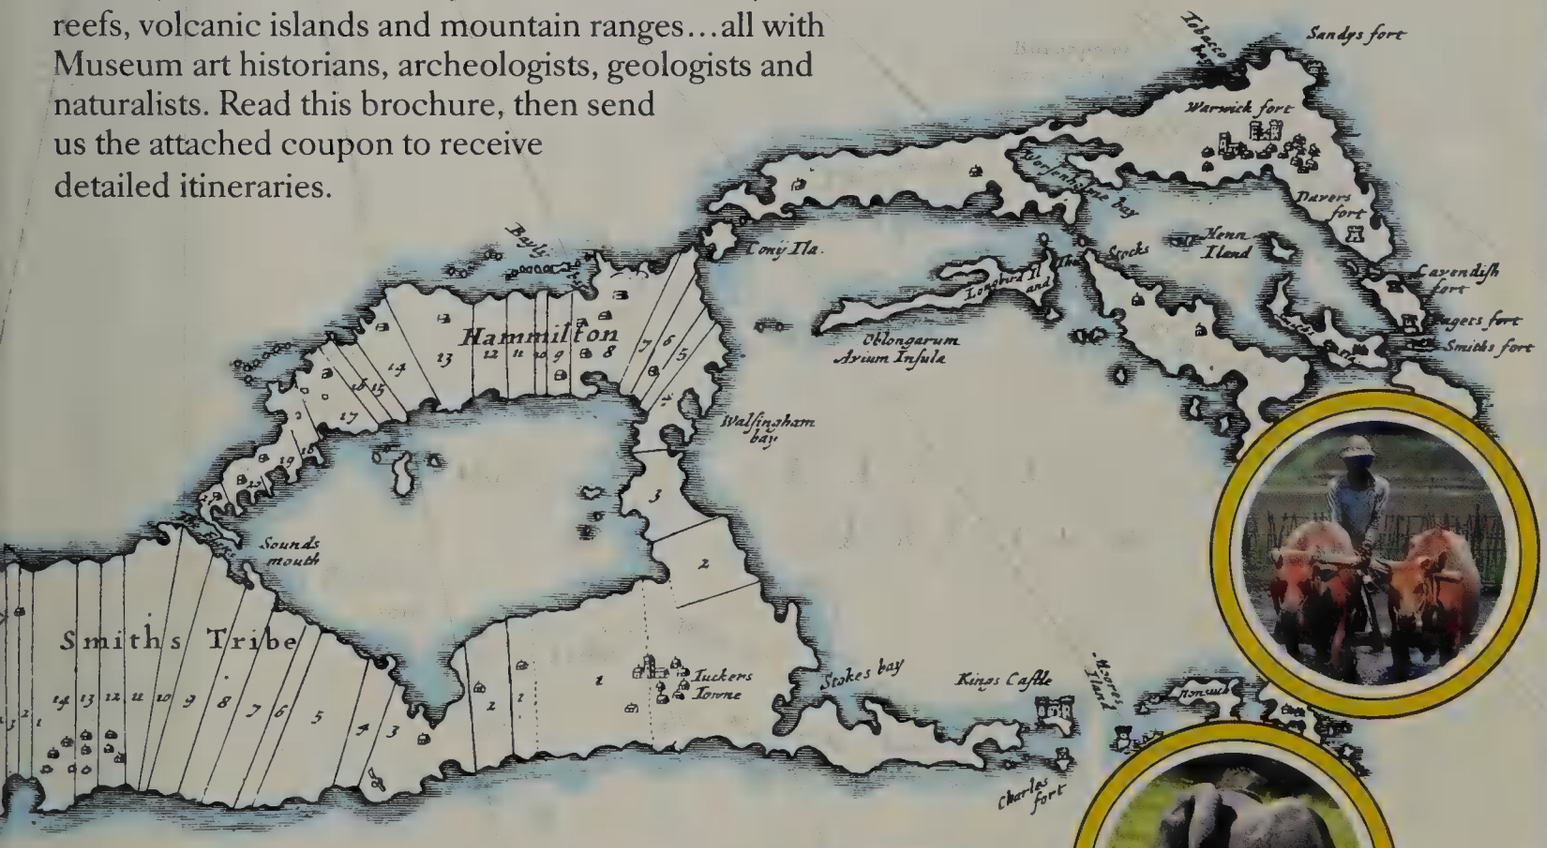
Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.

Special Tour Guide Pullout

AMERICAN MUSEUM OF NATURAL HISTORY

1986 DISCOVERY TOURS

Discover the world's outstanding ancient sites, architecture, traditional cultures, exotic wildlife areas, coral reefs, volcanic islands and mountain ranges…all with Museum art historians, archeologists, geologists and naturalists. Read this brochure, then send us the attached coupon to receive detailed itineraries.



Itineraries: each tour is carefully designed by Museum staff to include the highlights of the destination plus many excursions to sites rarely visited by most groups.

Lecturers: accompanying each group are distinguished scholars who are eager to discuss your ideas and give you a broad as well as detailed background for each area we explore.

Cruises: our vessels are carefully selected to provide luxury, safety, and limited passenger capacity allowing you to disembark with a small group on each land excursion. Our largest cruise vessel has only 68 cabins, but all the amenities of the giant cruise liners.

Land Programs: only 12 to 20 participants join our lecturer and escort for indepth overland excursions.

Air Schedules: all of our programs quote international airfares separately, allowing you to deviate from the standard group flights and custom-design pre and post tour excursions.

Pre-departure Information: before you go, you will receive comprehensive materials covering clothing, currency exchange, medical suggestions, reading lists, guide books, documentation, etc.

Tour Operators: we select the world's finest travel companies to meticulously arrange and operate each exciting excursion.

Further Information: send us the coupon to receive detailed brochures with maps outlining the itinerary, prices, conditions, etc. Or call us directly at the Museum, (212) 873-1440. Our tours usually fill up quickly. If you wish, you may reserve places immediately by sending us an advance deposit for $250. per person (payable to the American Museum of Natural History) with a note indicating which tour(s) you wish to join. There is $25. per person cancellation charge for each advance deposit.

Special Museum Cruise

Voyage through Melanesia: New Guinea to Fiji
February 16 to March 6, 1986

Join Dr. Thomas D. Nicholson, Director of the American Museum, and other outstanding lecturers on a luxury cruise through the most intriguing island group in the world: New Guinea to Fiji. The cultural and natural history is extraordinary.

Exquisite artwork, fascinating traditions and unique performances (sing-sings) will be experienced on land and discussed while at sea with renowned anthropologists and art historians. Stunning coral atolls and volcanic islands will be explored with expert marine biologists and geologists.

You will travel by luxury cruise vessel, the *Illiria*, with only 68 cabins: the amenities of the finest giant cruise liners and the intimacy of your own private yacht.

The combination of an excellent itinerary, lecturers and cruise vessel results in a splendid experience. Join us!

If you wish to receive a brochure describing the complete itinerary and accommodations, call (212) 873-1440. Or complete the coupon attached to the general brochure (to the left), check "Voyage through Melanesia: New Guinea to Fiji," and send it to:

Dinty Moore of Lake Becharof

And other brown bears I've met along the trail

by Derek Stonorov

I've never had a brown bear touch me or anyone I've been with. Other than the ones I've tranquilized, I've never touched a bear except once, when I hit a friendly one with a snowball. I've met bears in the alders, bears on the beach, bears in the middle of streams, bears that were eating, bears that were sleeping, even bears that looked amorous. I've chased bears off moose kills and bears off dead seals; I've inadvertently separated sows from cubs. I've met bears of forty pounds and bears of half a ton. I've met bears on snow slides in the spring and bears in berry patches in the fall. I've interrupted their peace many times . . . but so far things have gone well. Karma? Perhaps. Luck? Lots of it. Respect? Certainly.

I have always kept track of my encounters with bears. The summers that I studied how bears communicated with each other at McNeil River in Alaska, I also kept an account of how they interacted with me. Immediately after a bear and I had separated, I'd write down the visual and vocal signals observed and the sequence they occurred in. I divided each encounter between the bears and myself into three parts. The first I called the identification phase, the second the aggressive display, and the third, for the purpose of gathering information on habituation, subsequent behavior.

The identification phase started when the bear began to do anything bears commonly do to identify strange objects in their environment. Facing toward me and sniffing were the most common indicators that the bear had sensed my presence and was curious. Sometimes it would stand up on its hind legs, in an apparent attempt to locate me visually. Bears in tall grass, as one would guess, are more apt to stand up than bears in open tundra. I have never found any indication that this standing up, no matter how dramatic, is a signal of aggression or of an intent to dominate. It is seldom used once identification has been made, except as a way of tracking an adversary at a distance. During this identification period, the ears would be forward and facing toward me, as if the bear was trying to figure out what I was by the sounds I made. The mouth could be seen opening and closing slightly. If I was feeling really cool, I would look through my binoculars and detect nostril movement. At this point sucking and blowing sounds would often be heard as the bear pulled in and expelled air, most likely trying to identify or locate my scent. In brown bear country, you can sometimes hear these sounds when you're in heavy cover—but never see the bear making them.

During the identification phase a bear would often circle me, apparently trying to find a spot where he could get my scent or a better view. This was far more common the first time I met a bear than afterward. Also, bears that were a hundred yards away did it more often than those that were closer.

At this point, if the bear moved toward me or away from me, that was the beginning of what I consider an aggressive display. Obviously, there is a good bit of overlap between what I call identification and what I call aggression because many actions signal more than one thing. Also, what I do is important. While I tried to keep my behavior simple and consistent—I either stood still or slowly backed away—even slight variations in how I acted often altered what happened. Usually, the display part was very short; the bear would move off doing nothing more than occasionally looking at me over its shoulder—mouth and nostrils moving, ears forward, and then back against the head. If, however, the bear decided to pursue me or at least come closer, I saw other aggressive signals: the classic stiff-legged look, a slowdown in movement, chomping with the mouth, loud growls, and perhaps a few short lunges.

If the bear now resumed what it had been doing before the confrontation with me, or if it stopped giving aggressive signals, I considered the final part, or the subsequent behavior phase, to have started. Even when the bear was the obvious victor, and forced me to move, about 85 percent of the time it moved to a new spot before resuming its activities. The distance a bear moved was not predictable. Two encounters between man and bear on the McNeil Tidal Flats demonstrate the extremes of behavior one can observe.

First Encounter

MAN: Walking on bear trail

BEAR: Eating sedge grass alongside trail

MAN: Sees bear, stops, stands motionless fifty feet away

BEAR: Senses man, stops eating, faces man for three seconds

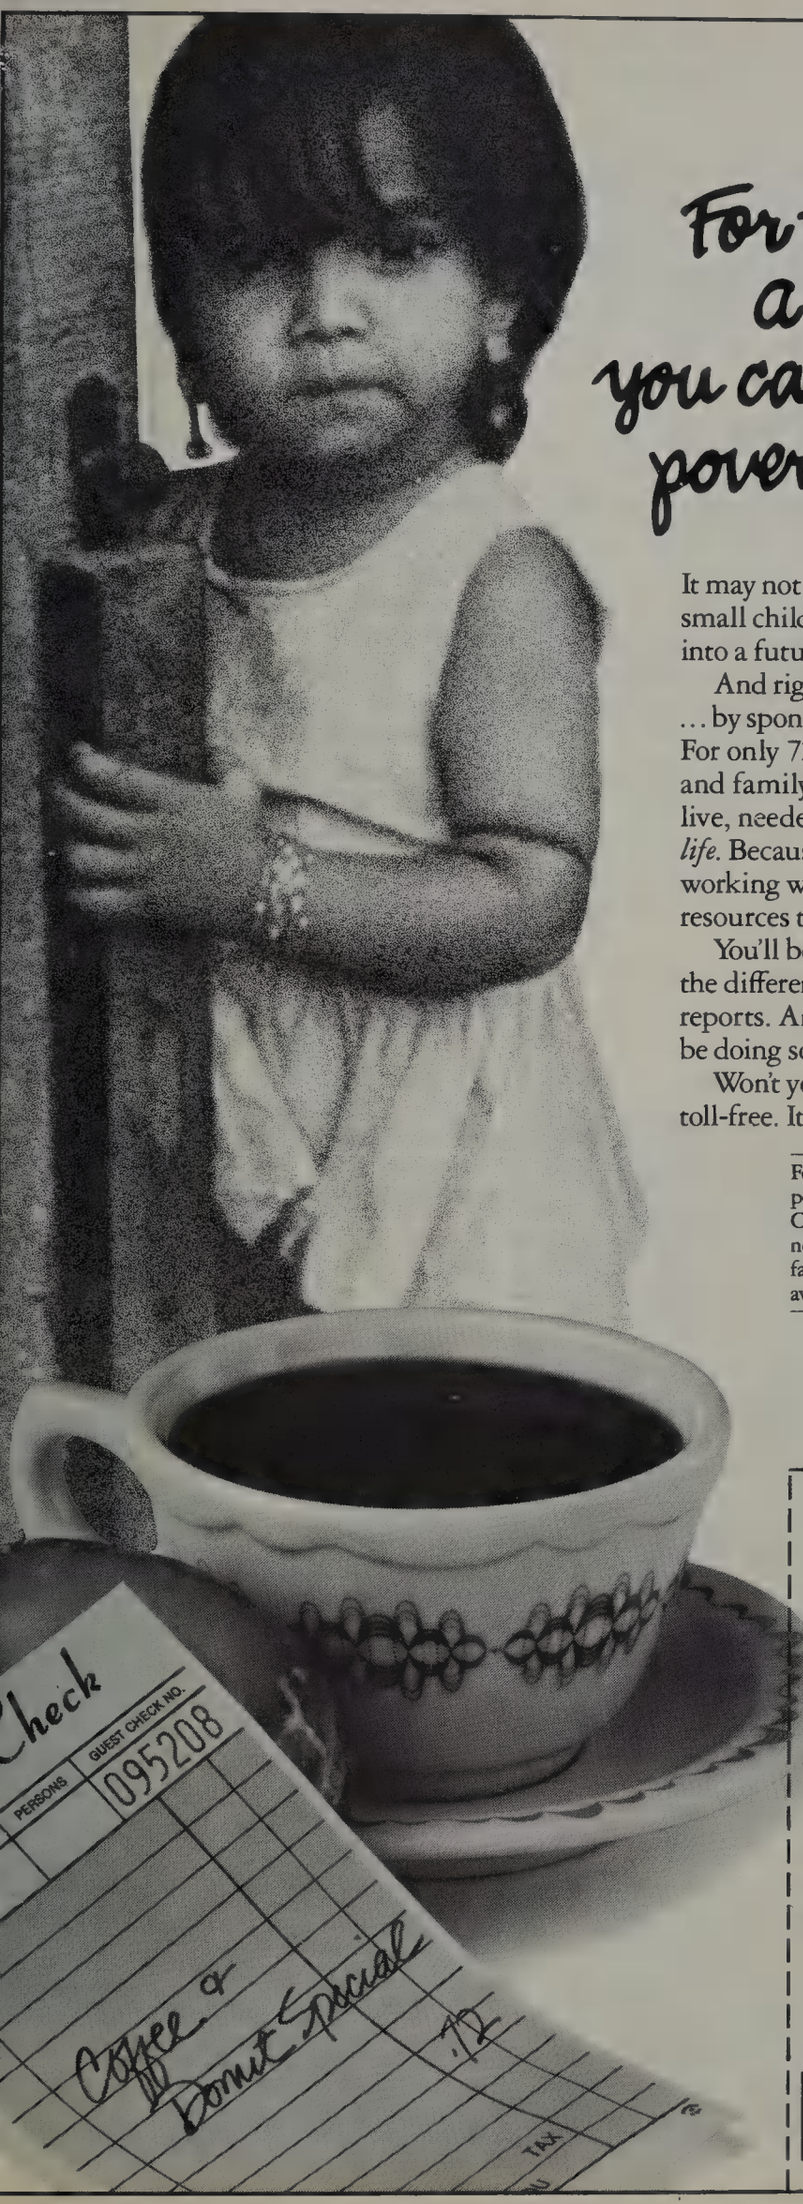
MAN: Remains motionless

BEAR: Turns head away, moves one hundred feet from man, sits down, resumes eating

MAN: Slowly moves away

Second Encounter

MAN: Walking on bear trail



For the cost of a morning coffee break, you can break the cycle of poverty for one small child.

It may not seem as though 72¢ will go very far these days. But for a small child like this, it can lead her out of desperate poverty and into a future of hope.

And right now, you can reach out and make that future happen ... by sponsoring one child overseas through Foster Parents Plan. For only 72¢ a day, you can make it possible for your Foster Child and family to have adequate food and clothing, a decent place to live, needed medical care, education ... *and the chance for a better life.* Because while you're helping, the child's own family will be working with Foster Parents Plan to develop the skills and resources they need to help themselves.

You'll be amazed at the difference you can make. And you'll see the difference for yourself. In photographs. Detailed progress reports. And heartwarming letters from your Foster Child. You'll be doing so much for that child ... and for so little.

Won't you help now? Simply mail the coupon today or call toll-free. It could be the biggest break a child ever got.

Founded in 1937, Foster Parents Plan will this year bring its unique, person-to-person program and effective services to over 236,000 Foster Children and their families in more than 20 countries. We are non-profit, non-sectarian, non-political, and respect the culture and religion of the families we assist. A detailed annual report and financial statement are available on request. Your sponsorship is 100% tax-deductible.

To start helping even faster, call toll-free:

I wish to become a Foster Parent to a: ☐ Boy ☐ Girl ☐ Either

Age: ☐ 6-8 ☐ 9-11 ☐ 12-14 ☐ Any age 6-14

☐ **Wherever the need is greatest,** or as indicated below:

☐ Africa	☐ Egypt	☐ Honduras	☐ Nepal
☐ Bolivia	☐ El Salvador	☐ India	☐ The Philippines
☐ Colombia	☐ Guatemala	☐ Indonesia	☐ Thailand

☐ Enclosed is a check for $22 for my first month's support of my Foster Child. Please send me a photograph, case history, and complete Foster Parent Sponsorship Kit.

☐ I am not yet sure if I want to become a Foster Parent, but I am interested. Please send me information about the child I would be sponsoring. Within 10 days I will make my decision.

☐ Mr. ☐ Mrs.
☐ Miss ☐ Ms.

You can do so much ... for so little.

BEAR: Eating sedge grass alongside trail

MAN: Sees bear, stops, stands motionless one hundred feet from bear

BEAR: Senses man, stops eating, stands on hind legs to look

MAN: Looks at bear, remains motionless

BEAR: Staggers backwards, drops, and runs

MAN: Continues walking on bear trail

BEAR: Still running when glimpsed one mile off

The intensity of the interactions between man and bear lessens as the two become used to each other. Bears are intelligent animals, and after a few meetings with humans they are likely to calm down (as do the humans) and tolerate people at close range. This may be a positive change, but one must be constantly aware that if a bear suddenly perceives you as a danger, there may not be much time to react.

There are at least three reasons a bear might respond aggressively to a person—to defend its individual distance or personal space, to defend its young, or to defend its food source.

It is difficult to measure individual distance—the space around an animal that if violated will cause the animal to attack or flee. Sometimes the distance is twenty-five feet, sometimes hundreds of yards. I have found that the biggest variable is how the bear becomes aware of me and vice versa. That I can't control. If I wake a bear that has been napping in the alders and it goes crashing off while I am still fifty feet away, that's one thing. I can't really compare it to a situation in which a bear in a tidal meadow spots me from six hundred yards and lets me approach to within one hundred yards before slowly moving off. In encounters that are alike—man meets bear in tidal meadow or man meets bear on open hillside—there seems to be a correlation between how far apart the two parties are when they become aware of each other and the subsequent intensity of the bear's reaction (and likely the man's too!). Whether or not a bear has gotten used to humans also has an effect. The safest thing to say is that the area a bear will defend is directly dependent on the individual bear, the situation, and how the bear perceives the threat.

If you violate a bear's personal space, you may get a reaction; but if the bear is with young, it becomes much more likely. This is the most common cause of damage between man and bear. One reason that a sow is so fierce in her defense is that large male bears are sometimes cannibalistic. If given the chance, an old male may pick off a cub. Another reason is that on occasion bear cubs become the prey of other animals. Twice I have seen wolves approach sows with cubs; the wolves were driven off. I'd venture to guess that a first-year cub wouldn't be much of an adversary for a full-grown wolf that might outweigh it two to one. Both times I saw them, the wolves were fishing and not stalking, but the sow still saw fit to charge and chase.

A threat to its food could provoke a bear, too. In my experience, bears have left their food rather than tangle with me, but I know this is not always the case. Again one must be aware of the variables. How satiated is the bear? What is its social status? Some bears feeding on dead animals are likely to charge anything that moves; on the other hand, a timid subadult may run from a passing raven.

Defense of personal space, young, or food are all reasons a bear might become aggressive, but these don't cover every circumstance. In some of my encounters with bears, the bear's motivation has been difficult to explain.

Give a kitten a ball, place a new object in the cage of a laboratory rat, and it is easy to see exploratory behavior. I believe that some man–bear interactions begin when the bear simply becomes curious about the man and decides to explore. Many biologists, myself among them, believe that it is to the biological and evolutionary advantage of an animal to explore its environment. This behavior has survival value; some aspects of it can be seen in the predatory behavior of carnivores. However, what starts out as exploratory behavior need not end in a charge.

Many times an encounter between me and a bear started when the bear, noticing I was observing it, began investigating me in turn. This type of behavior seldom developed into a display of much intensity; most of the incidents could hardly be termed aggressive. Commonly the bear would approach where I was sitting, sniff, face me, turn, and depart. While the bear sniffed and looked me over, I often got the feeling from the way it moved that it was making up its mind whether to move closer or flee. Sometimes a bear would seemingly test my mettle—or its own—and growl and stalk around in a disgruntled way before departing. Only once did a large bear approach me like this, and never has a sow with cubs done it. Usually the bears that spot me and come over are juveniles; possibly they haven't learned their manners yet. One, which I named Dinty Moore of Lake Becharof, saw fit to approach and threaten me four times in ten hours. Holy Joe and Henderson—two young bears I believe were litter mates—also of Lake Becharof—frequently hung around me, although once they tried a bluffing charge from sixty feet out. The motivation of a bear in this type of situation is difficult to assess, but in twenty-five cases that I have documented, in which I was in the open and the bear came at me, I am confident I was seeing exploratory behavior.

A predator–prey relationship is another possible reason for man–bear encounters. Tragically, some people have been killed and eaten by bears. While this almost never happens, the fact that it has shows one more aspect of the complicated organism that is the brown bear.

Whether a bear would ever intentionally prey on humans is a subject of debate, but there is little doubt that if you run quickly from a displaying bear you may trigger a chasing response that could lead

Larry Aumiller; Bruce Coleman Inc.

Alaskan brown bears near McNeil River

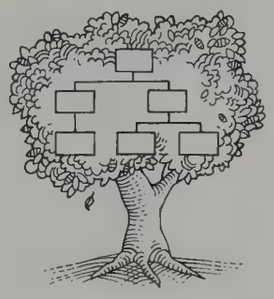
a truly predatory act—that is, killing nd even eating. I have no data on this nasing instinct, a bit of behavior that is eported for most predatory species, but I elieve in it enough to have never run flat ut from a displaying bear. And on three ifferent occasions that I know of when a rge bear killed a smaller bear, the victim ad run away from a confrontation and as dragged down.

One other, lesser-known reason bears ometimes confront people is social status. human in a bear's environment is likely be tested and treated like a bear. This is he reason that if you see a large male bear alking down a trail and you are going gainst traffic you should give him room. is normal manner with other bears is to eep moving, head down, ears back, eyes the stranger, frontal body orientation, nd perhaps a growl. This is common be-avior. Large males are used to dominat-g a situation and are quite willing to in-rease the intensity of their display in rder to proceed. If coming toward you hile making the above-mentioned signals enough to move you, the bear will pass by. If it takes a knock down, drag-out ght to move you, the bear will do that, hen pass on by. I once saw Killer, the top-nking and largest male at McNeil, re-ove a large male called Patches from a ear trail by picking up the 750-pound ear in his mouth—removing a six-by-ght-inch piece of hide in the process—ushing him down a bank, and then pro-eeding to a fishing spot as if nothing had appened. What appeared to me a hercu-an task, and a very stressful situation, dn't even delay Killer's lunch.

While it is unpleasant to have a bear ominate you, it is better to be dominated nd treated like a lesser bear than to be aten or mauled. Usually, human victims bears are hurt but not killed, and the ears leave after a few seconds of contact. his leads me to believe that most of the me the bear is treating the human as it ould another bear, using ritualized bear ehavior. Unfortunately, humans can be riously injured by what, for a bear, mounts to a cuff or a nip. On nine occa-ons I have seen sow bears bite fleeing ubadults on the bottom after the sub-dults came too close to them. These were ot playful nips—they would have done in nything weaker than a brown bear, and ey were all preceded by full-blown, gh-powered, forty-mile-an-hour, earth-aking charges, and all manner of ntagonistic signals.

All of this raises the question of how umans should behave around brown ears. When I unexpectedly meet a bear, e first things that go through my mind

THE BEST GIN GROWS ON TREES.



The driest and most delicate gin of all, in fact, comes from the tree at the left: the family tree of James Burrough, a distiller in 19th century London.

Burrough had a basic philosophy: if you want a thing done right, do it yourself. Not a single distillation of his Beefeater Gin left his distillery till it was approved by James himself.

He wasn't much of a delegator, but he made a beautiful gin.

His philosophy has been handed down through succeeding generations of the Burrough family, who still supervise each day's run and approve each batch of Beefeater before it leaves the distillery.

The apple never falls far from the tree. For which gin drinkers to this day are profoundly grateful.

Chrysler creates LeBaron GTS. The American sedan

The design is bold. Sleek, daring aerodynamic lines.
The performance: heart-pounding.
This is GTS. A new kind of LeBaron—a performance
LeBaron engineered to compete with Europe's best sedans.
And it does. When you equip it with turbo, special sport
handling suspension and 15" wheels, LeBaron GTS is faster
from 0 to 50 than BMW 528e and Mercedes 190E.
But this LeBaron offers more than pure speed.
Through the twists and turns of the slalom and
around the cornering track, it outperforms the legen-
dary BMW. In braking, it outperforms BMW again.

hat outperforms BMW 528e and Mercedes 190E.

And yet this disciplined road car is a comfortable
n. For five. LeBaron GTS Premium's cabin is marked
dvanced electronics and functional luxury. And
ble leathers can be fitted to its ergonomically
gned seats.
Even its Protection Plan is outstanding: 5 years or
00 miles** on turbo, engine, drivetrain and outer-
y rust-through.
LeBaron GTS would be impressive at any price.
10,000 less than the least expensive of the Euro-
competitors, it is stunning.

*Overall results of USAC tests vs. standard equipped 1987 competitive test models.
**Whichever comes first. Limited warranties. Deductible applies. Excludes fleet leases. Dealer has details. †Based on sticker price comparisons of rent cars. Standard equipment levels may vary.

We engineered it to compete with
Europe's best. It does.*

LE BARON GTS

Chrysler Corporation

are: Does the bear have enough room to move, and does the bear think I have it trapped? A sow with cubs just might not be willing to take her family past four other bears to increase her distance from you. A small bear may have just lost a battle with a larger foe and may figure that it is easier to get by you than return and be beaten again.

Once, three friends of mine and I were walking home on the beach when we spotted a bear several hundred yards away coming toward us. There were sheer cliffs on one side and the incoming tide on the other, the proverbial rock and a hard place. I felt that because there were four of us and it was a very small bear, it would turn and run from us. We were in a hurry as high tide made several creeks impossible to ford, which, in turn, made the walk back to camp a mile or so longer. The beach was perhaps 30 feet wide. We very foolishly kept on going, yelling at the bear. He kept on coming. We kept on yelling. At 150 feet he began to display, growling and working his mouth. We stopped our progress and all backed up as a unit. He came on but did not shorten the distance between us. Finally, after perhaps three minutes and 100 yards, we came to a break in the cliff and he got opposite us; he broke into a run and maintained that run for a good 300 yards. What was on that bear's mind, I do not know. I do know that we were wrong to initiate the confrontation. You can't force your time schedule on a bear. If you are willing to sacrifice slightly—a ten-minute wait or a mile extra walk—your chances of being hurt will be vastly reduced.

The most important thing to remember in brown bear country is that the only wild animal out there is you. You stick out like a sore thumb to the local inhabitants, and besides that, you apparently stink and wear a raincoat. You are the only animal around that lacks interspecific tact and the speed to escape interspecific strife.

And another thing: Give the bears a break, leave your watch at home. One of the most common reasons I have heard for forcing a bear to move is, "Well, I was in a hurry." In a hurry to do what? Die? Kill the bear? Relax and go slowly. Find a good berry patch to graze in for a while if a detour around a bear is impossible. Forget the Judeo-Christian ethic that places men above all. Treat the bear at least as an equal, not as a rug. Before you depart on a wilderness trip, get a little philosophical about bears and what they mean to you and the world.

I also keep out of the alders and places that are hard to see into. Bears like to bed up in cover and have been known to take unkindly to being awakened. It is common for bears in cover to completely panic when they smell a human and to take off not realizing or knowing where you are. They will come by at a great rate. If you are in the way, you could be pushed, trampled, or else just scared to death. If you have to pass through cover, make some noise. You don't have to disrupt the cosmos, but it doesn't hurt to give the bear some warning.

Bear trails are bear highways. Some of them have been used extensively for hundreds of years. Bears are not random walkers. They don't just go anywhere. If you see a bear coming and you don't want to talk to him, move off the trail and chances are he will go right on by. If you are going to stay in one area, try to use the same trails as much as possible, even the same trails at the same times. Bears space themselves from each other by space and time. People should do the same. Once the bears learn your routes they will keep clear. Don't camp on bear trails. This is one of the oldest mistakes in the book. Look around before pitching your tent. Beaches, stream banks, and lake shores all usually have bear trails. Keep off them or if you insist, leave something in the trail so the first thing the bear discovers isn't you. It goes without saying that the height of foolishness and bad manners is to camp without a tent in a bear trail. Better to have the bear sniff the tent prior to sniffing your face.

Cleo Creek runs into Lake Becharof about a mile south of the cabin where we lived. There's a sand bar at the end of the creek. To get to Cleo Creek, you walk out the front of the cabin, turn left, and proceed along the lake shore, fording Cleo Creek at the sand bar. About one hundred feet past the mouth of Cleo Creek is an old cabin. We used to climb up on the roof there to watch the bears fish.

One afternoon I watched a bear that was new to me chase every regular Cleo Creek bear off the bottom half-mile of creek. The new bear, a medium-sized male, chased fish when not chasing other bears. He'd go roaring upstream, and the shallow water would boil as hundreds of salmon tried to escape. A few minutes later, he'd be back at a gallop, the salmon swimming downstream this time to get away. Sometimes a fish would beach itself in its escape attempt and the bear would grab it and disappear in the alders for a meal. It was beginning to get dark, and the bear had made one of its upstream runs when I decided to go home.

I was just crossing the creek at the sand bar when the bear came back downstream. At fifty feet he stopped, looked, and began a dance of displeasure. His legs got stiff, his ears went back, and he made chomping noises with his mouth. I began to back out into the lake. He made a short charge out into the shallows but stopped and then moved laterally toward me for a few steps, keeping his eyes on me all the time. I backed out into the lake until the water came over the top of my hip boots and the bear just growled and watched me. I began to work my way up the shore away from the creek mouth. Abruptly the bear broke off the encounter, turned, and trotted off up Cleo Creek and out of sight. I got back on the beach and started home, not even bothering to empty the water from my boots. A hundred yards up the beach, who should I notice paralleling my progress home, perhaps one hundred feet away, but the bear. He stayed with me for ten minutes or so, quietly walking and watching. Finally he just disappeared and I went on to the cabin.

For that ten-minute walk home, the bear and I were in touch. When he charged me, I was scared as hell, but by the time I got near home I was sort of digging it. The next morning at 6 A.M. the bear again met me at the mouth of Cleo Creek—this time I had my wife with me—and he again charged, but after we subordinately waded into the lake he turned and went splashing off upstream.

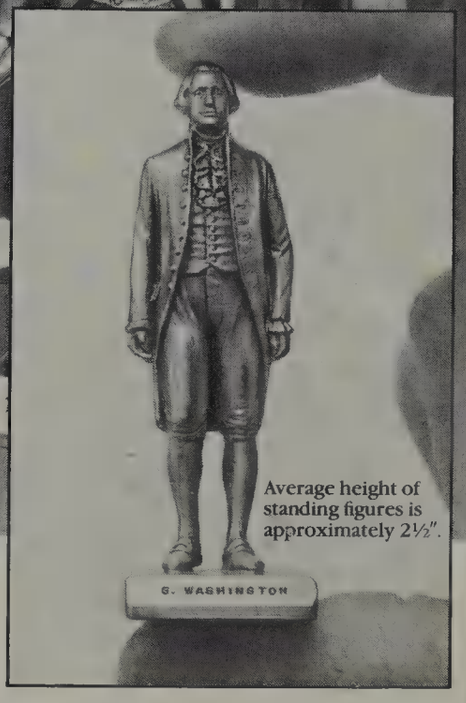
All of which reminds me of the time in the summer of 1967, right up near the top of Bear Creek. I had been walking and looking for bears all day and I was hungry, so I sat down to eat a peanut butter and jelly sandwich. I had only taken a bite or two when a bear stuck its head out of an alder patch and began to click its teeth and lick its lips. Well, my gun was miles away back at camp, my Swiss army knife didn't look like a bear sticker, and I never felt I could kill a bear with my bare hands; and since the bear didn't look like it was going to leave, I gave it half my sandwich. I tossed it and the bear caught it and swallowed, much the same way a frog takes in a fly—I don't think it chewed. It must have liked whatever fleeting taste it got because it walked over and tore the other half of the sandwich out of my hand, taking two fingers and my thumb along with it. I turned to run, but the bear knocked me down with one blow of its front paw. The last thing I remembered was its rotten breath as its jaws closed on my head. And then? . . . and then? . . . Well, the truth of the matter is the bear killed and ate me.

Derek Stonorov does research on bears at Lake Becharof and the McNeil River in Alaska. This article was adapted from a work in progress.

Presenting

The American Presidents Collection

In Fine Pewter



Average height of standing figures is approximately 2½".

Issued In A Single Limited Edition Of Only 5,000 Collections.

- Unique, handcrafted sculpture of every U.S. President.
- Richly detailed in fine, satin finish pewter.
- Hallmarked and registered. Certificate of Authenticity.
- Custom American solid wood display unit at no additional charge.
- Remarkably priced at only $19.50 each.

In celebration of our nation's 50th Presidential Election, the New England Collectors Society proudly presents "The American Presidents Collection" in Fine Pewter, a fascinating personal museum of Presidential sculptures.

Issued in a single, Limited Edition of only 5,000 collections, every American President in the collection is an intricately detailed, original sculpture of Fine Pewter, perfectly proportioned so that the sizes of the sculptures vary according to the height and physical stature of each President.

Especially commissioned by Reed & Barton, America's most prestigious silversmiths since 1824, "The American Presidents Collection" is an impressive work of art sure to be enjoyed today and cherished for generations.

To make this rewarding acquisition simply return the accompanying reservation application.

The New England Collectors Society is a subsidiary of Reed & Barton, fine silversmiths since 1824.

"The American Presidents Collection" G39

The New England Collectors Society
237 Saw Mill Road, P.O. Box 464
West Haven, CT 06516

Please accept my reservation for **"The American Presidents Collection"** consisting of 40 presidential sculptures crafted in fine pewter, to be sent to me at the rate of one per month. The guaranteed issue price of each sculpture is $19.50 (plus $1.95 shipping and handling).* I will receive a custom designed American hardwood display unit and informative reference literature at no additional charge.

I prefer to pay as follows:

☐ Enclosed please find my payment of $19.50 plus $1.95 for shipping and handling* for the first sculpture. I will be billed for additional sculptures on a monthly basis.

OR Charge each sculpture as it is shipped to my:

Ancient Bristlecone Pine Forest, California

by Robert H. Mohlenbrock

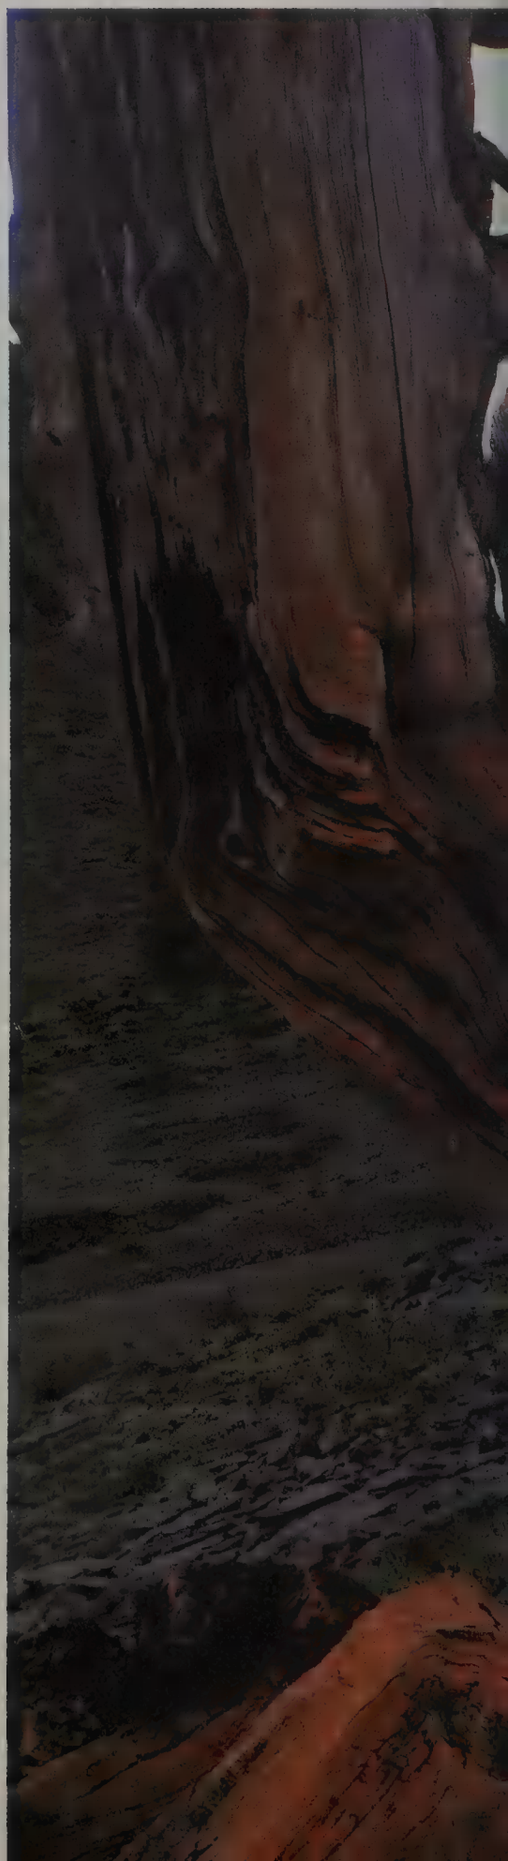
During each growing season, a tree adds a layer of wood to its trunk and branches, creating the annual rings we see in a cross section. The new wood cells arise from the living tissue that lines the bark. In the spring, when it is moist, the tree devotes most of its energy to growth; at this time, the new cells are relatively large, but as summer progresses, they get smaller and smaller. In the fall, the wood cells die, and no new cells are added until the following spring. The contrast between the last layer of small cells from one year and the first layer of large cells the next year is usually strong enough to make ring counting rather simple.

Early this century, A.E. Douglas of the University of Arizona observed that a wide ring, at least in some species of trees, indicated that the wood was formed during a wet year, whereas a narrow ring denoted a dry year. Archeologists, botanists, and foresters used this discovery to develop the science of dendrochronology—the dating of past events or climatic changes by the study of growth rings. Climate patterns in specific geographic areas can be ascertained by examining ancient living trees, and if suitable fragments of wood that overlap in age are found, the procedure can be extended back in time. Samples of unknown age can then be dated by matching their growth patterns with the established sequence of tree ring growth. For example, dendrochronologists have dated Pueblo Bonito, a prehistoric Indian settlement in New Mexico, back to the seventh century by analyzing the wood used in its construction.

In the 1950s, hoping to determine exactly when ancient droughts occurred in the Southwest, wood anatomist Edmund Schulman of the University of Arizona began a systematic search for the region's oldest trees. He knew that the oldest California redwoods were about 2,200 years old and that some western junipers in Yosemite were nearly 2,500 years old. Some giant sequoias have been living for more than 3,000 years; the famous General Sherman tree, for example, may be as much as 3,500 years old. But Schulman wanted to find still older trees. In 1953, while exploring the White Mountains on the California–Nevada border with Frits Went of the California Institute of Technology, Schulman stumbled onto a promising grove of weathered, gnarled bristlecone pines, most of which were clinging to life by a mere ribbon of living bark.

For the next several years, Schulman studied the growth rings of these trees, which looked liked living driftwood. Using a boring tool, he removed thin cylinders of wood from the trunks and counted their rings (although this procedure leaves a small opening, the pine's capacity to exude resin quickly into the wound prevents subsequent decay). The rings were minuscule, and counting them was no easy matter. Some of the trunk tissues had eroded away, and those rings that were left usually were not in neat concentric circles. The band of living tissue in an old, eroded stem sometimes grew at right angles to its original rings. Schulman had to match the rings of one tree with those of others that had the missing section or that were undistorted. His efforts were amply rewarded, however, as the remarkable ages of some of these trees began to emerge. The first tree Schulman found that was more than 4,000 years old he called Pine Alpha; later, he identified a 4,600-year-old denizen and christened it Methuselah. (During the 1960s, forester Donald Currey discovered a bristlecone pine near Wheeler Peak in eastern Nevada's Humboldt National Forest that is more than 4,900 years old!)

Several years ago I went to the Ancient Bristlecone Pine Forest, part of California's Inyo National Forest, to see Schulman's trees for myself. A Forest Service parking area is provided for the well-kept hiking trail known as Methuselah Walk, which circles past many of the oldest trees, including Pine Alpha and Methuselah. (I found that a leisurely pace was advisable to avoid exhaustion at the 10,000-foot elevation.) At the time I thought that any organism that lived longer than the norm had to have optimal conditions going for it. For plants, these conditions would be adequate moisture, moderate temperature, continuous sources of nutrients, and protection from severe weather. When I stood looking at Methuselah, I



A bristlecone pine in California's White Mountains
David Muench

knew I had been wrong. The cold was bone chilling (even in July), the patchy pockets of soil showed little evidence of moisture, and the wind battered my body with repeated gusts.

The bristlecones, along with the similar limber pines, dominate a subalpine coniferous forest that extends from about 9,500 feet up to timberline (about 11,800 feet), mostly within the western Rocky Mountains. The White Mountains, where Schulman found his trees, lie in the "rain shadow" of the towering Sierra Nevadas, which are to their west. Cyclones, moving inland from the Pacific Coast, shed their moisture before reaching the west slopes of the White Mountains, leaving only strong, dry winds that whip across the mountainsides. Rainfall is less than twelve inches per year.

The greatest concentration of very ancient trees is near the crest of a ridge, in exposed patches of dry, rocky, dolomitic limestone. The limestone is relatively cool because the light gray or even white ground surface reflects more solar radiation than nearby outcroppings of sandstone or granite. In addition, nutrients are readily leached from the porous dolomite. Yet under these harsh conditions, the trees here survive to extreme age. Mature pines that grow on sandstone or in protected areas are neither as misshapen nor as old.

Ancient Bristlecone Pine Forest

Joe LeMonnier

Bishop, California 93514

The longevity of the pines appears to depend on their ability to develop and maintain a special growth habit. Trees 1,500 years old or older usually have only a narrow strip of living bark on the trunk and only a few living twigs and needles on one remaining live branch. The reduction of living tissue to a single strip results partly from weathering and abrasion by soil particles that remove the bark from the upper surface of the roots and partly from repeated loss of foliage and twigs on the windward side of the tree. These old trees grow exceptionally slowly, even during their very first year. Most of them produce only an inch or less of growth rings in a century. Schulman found one gnarled tree that was only three feet tall and had a trunk diameter of three inches; it was 700 years old.

Bristlecone pines that receive more moisture, more nutrients, and greater protection show comparatively fast growth during their early decades. These "normal" trees produce an increasing volume of new wood each year to maintain a constant annual increase in thickness around their symmetrical trunks. Like most trees, they become less efficient at absorbing and metabolizing carbon dioxide as they age. Consequently, they become uniformly sickly and die. But although most of an old bristlecone pine has already died over the centuries, a small living part of it remains healthy. Such a tree is able to maintain a constant ratio of living to nonliving tissue almost indefinitely with little expenditure of energy. During years with severe weather, minimal metabolic activity is required to keep the tree alive.

The durability of the exposed, dead wood contributes to the tree's longevity. In most trees, dead tissue ultimately rots and the tree falls, but in the old bristlecones, the nonliving wood remains sound throughout the life of the tree. This resistance may be due to the (as yet unexplained) greater than usual concentration of resin canals in the trunk and to the absence of wood-destroying fungi, which apparently cannot tolerate the cool, dry environment where old bristlecones grow. Fast-growing bristlecone pines in less rigorous habitats tend to develop heart rot after reaching a diameter of fifteen inches or so.

Other favorable conditions may also help explain the bristlecones' longevity. In the oldest groves, the trees are widely spaced, reducing or eliminating competition of tree roots and crowns. And the dolomite retains more moisture than either sandstone or granite. Consequently, the timberline on dolomite doesn't begin until about 11,800 feet, whereas the growth of trees on sandstone and granite ceases at 11,000 feet. Finally, at high elevations the dolomite that underlies the bristlecones supports very little understory vegetation, thus reducing the possibility of ground fire.

Jeff Gnass

An ancient bristlecone may contain no more than a thin ribbon of living bark.

A few miles north of Methuselah Walk is another impressive group of bristlecone pines—Schulman Grove. The Patriarch, the largest bristlecone pine in the world, grows here. Thirty-eight feet wide and forty feet high, the Patriarch is a tree to behold, yet scientists say it is a mere youngster, only about 1,500 years old.

At this point in history, the ancient bristlecones are a phenomenon, but experts predict that most of the old pines will succumb in a few centuries. Trees like the General Sherman sequoia, which, unlike the bristlecones, live under evident optimal conditions, seem destined to become the longevity champions. At 3,500 years, General Sherman is in the prime of life, showing little sign of deterioration. If conditions remain favorable, it may survive for another 3,000 years.

Most English farms were enclosed between the fifteenth and eighteenth centuries. Only Laxton, in the Midlands, escaped the enclosure movement, perhaps because of its relative isolation.

The Observer, London

Laxton's Open Fields

Neither fences nor hedges divide one person's land from another's—a system of farming that dates back to the Middle Ages

by Donald D. Donihue

When Richard Rose sets out to plow his father's land in the West Field at Laxton, it takes him all day. Not because his father's holding is so great that a full day's labor is required—there are only five and a half acres—and not because of antiquated tractors and farm machinery. It is, rather, the consequence of the peculiar way in which the land is worked by Laxton farmers—a pattern that goes back before the Middle Ages in England and northern Europe. As Richard's father says, "We've grown accustomed to working it that way."

Many fields in the English Midlands used to be vast and open; neither fences nor hedges divided one person's land from another's. Gradual enclosure of the open fields began in the fifteenth century, transforming English rural society. By the last part of the eighteenth century, when the Industrial Revolution was almost complete, the English countryside had turned into a landscape of smaller fields, hedges, stone walls, and scattered farms. Thousands of people moved from farming villages and crowded into cities like Nottingham to find employment.

Only one village in England escaped the complete enclosure of its open fields: Laxton, about an hour's drive from Nottingham and reachable only by a network of narrow roads. One of the reasons for its survival as an open-field village is its very isolation. Only here in Laxton do English farmers still tend their fields according to rules formulated by neighboring farmers during the Middle Ages.

Life in Laxton today, with its population of 280, is not very different from life in any small village community of the Western world in the late twentieth century. The John Deere Company is a familiar supplier of basic farm implements. There is contact with the outside world through television and through children who have taken up life in more economically rewarding places. A number of residents commute to work in nearby towns or coal fields. Children are bused to school in neighboring villages. Farmers are always on the lookout for additional income, and this may mean active participation in agricultural schemes of the European Com-

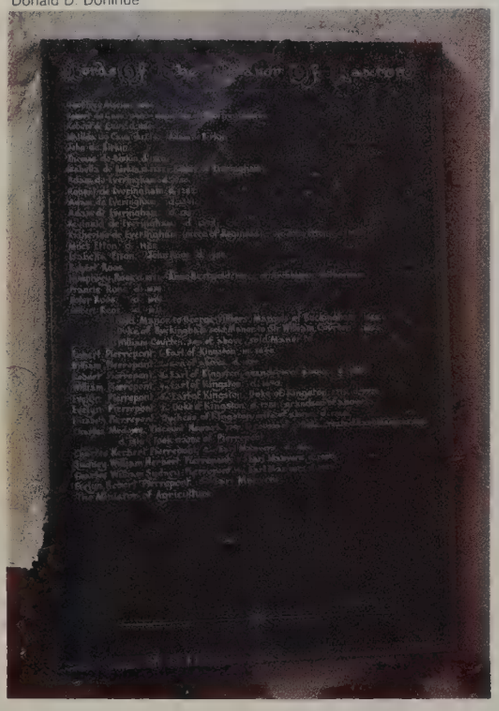
Donald D. Donihue



mon Market. And modernity has made its way into the heart of the village in many other ways. Only the manner of working the land seems caught in a time warp, unable to let go of the Middle Ages.

To be sure, there are a number of silent reminders of the past as one walks down the streets of the village. For example, one barn, constructed out of brick, has the date 1760 built right into the brickwork, while farther down the street, a house of the same kind of construction is dated 1748. On the north edge of the village, where the land rises, one finds the remains of a motte and bailey castle (a primitive type of castle built on a hilltop)—one of the many that dotted the English countryside during the reign of William the Conqueror in the eleventh century. Today all that survives of the castle is a mound of earth and portions of the ancient rock wall breaking out of the earth.

The most striking feature of Laxton today is what surrounds the village on three sides. Here three great, open fields—the West Field, the Mill Field, and the South Field—continue to be the source of livelihood for farmers and their families. Over a three-year period, crops are rotated among the fields, just as they were in the Middle Ages. In a given year the West Field is planted in winter wheat, the Mill Field is the fallow field, and the South Field is sown in spring corn. During the following year, the West Field will be the fallow field, the South Field will bear winter wheat, and the Mill Field will bear spring corn. And so it continues, year after year, as it has for centuries.

There is another medieval pattern that the farmers have not relinquished—and that is the manner in which land is held in the common fields. A family's holding is not all in one place in any one field. Instead it is scattered among all three open fields in narrow strips. Bill Haigh, who runs a dairy on Manor Farm in Laxton, will tell you:

> I have land in all fields—all three fields. I have three in South Field, and I have four in Mill Field, and I have just one in West Field. That's what my open field land is; so I've around twenty-seven acres.

Haigh's situation is typical of the eighteen farmers who have holdings on the Laxton estate. To the modern eye, it is an extremely awkward and ineffective way of holding land. That's why it takes so long to plow and harvest one's acres. One of the farmers remarks (but without complaint): "There's all that equipment to move around from strip to strip."

This peculiar style of holding and working the land forms a continuous thread between previous centuries and the present. A map of Laxton, drawn in 1635 by Mark Pierce and now housed in the Bodleian Library at Oxford University, depicts how farmers worked—and still work—their scattered strips of land. Pierce also illustrated the closely knit social life of the villagers—plowing together, harvesting together, herding flocks together, and even stalking the wild deer on the Laxton estate together.

The farming year at Laxton is built around the three open fields. The year begins in the fall, with the sowing of the winter wheat field. At the same time, the field that is to be planted with corn in the spring is plowed. The third, or fallow, field is open to sheep, so that they can graze on the stubble of the preceding year's crop. The fallow field is the counterpart of the common field of previous centuries, the

Every autumn, a field jury inspects and redefines the boundaries of the farmers' strips, making certain that no one has encroached on the holding of another.

Donald D. Donihue

Right: A heavy wooden stake, hammered into the ground by a field jury member, will designate the line between a farmer's plowed strip and the grassy pathway that is meant for use by everyone.
Below: Laxton farmers take great care not to plow too far onto the grassy paths—although even without markers, the farmers know the boundaries of their individual strips.

Both photographs by Robert Holmes

place where livestock of the entire village could be let out to graze. "Breaking" the field used to be a big event in medieval villages. When all the crops had been taken from a field at the end of harvest, the church bell would ring on a set morning, and everyone would know by the sound of the bell that sheep could be grazed on the common field.

We see in the fallow field one of Laxton's adaptations to modern times, however. No longer does the field lie fallow the entire year as it used to when a rigid three-course rotation was in effect. In 1968 the village voted to "crop" the fallow field, permitting tenants to grow a fodder crop there. In many ways this made much sense, because it was no longer necessary to idle a field in order to allow it time to gather strength to bear another crop. Modern fertilizers and farming methods had rendered obsolete the inflexible three-course rotation and it was not economical to continue the practice. But the change came slowly and with difficulty—a rare giving-in to modern times.

The plowing of these scattered strips is an interesting sight. Each farmer moves his tractor off the grassy pathways, or sykes, leading through the fields and onto his strips. Great care is taken not to plow too far on a strip, thereby encroaching upon another's land. One must also be careful not to plow too far onto the headlands and grassy roadways, thus diminishing over the years those access routes that are meant for use by all.

In early November, seed is sown in that year's wheat field. By the end of the month it will be a sea of green shoots sweeping across the rising and falling open field. Also at the end of the month the wheat field will undergo an annual inspection by the members of the field jury to assure that all the boundaries are intact and that no one has encroached on the holding of another.

Winter snow can be deep in Laxton. The pace of life slows. Still, there are cattle and other livestock to be fed and cows to be milked. Spring brings a renewal of activity. Ditches have to be cleared of brush, and cattle that were fattened over the winter must be taken to market in nearby Newark-on-Trent. The grass on the pathways of the fields grows again. On a midsummer's day it will be sold to the highest bidder at an auction in the village, as has been the case since the 1780s. Harvest follows in the summer, when machinery moves into the fields and onto the strips. What used to take weeks is now done in a matter of days. Wheat is separated from chaff and sent to storage.

When the harvest is done, the field that bore the year's wheat crop is open again to livestock, which forage among the stubble. The year has come full circle.

The management of the Laxton estate is similar to that of many large agricultural enterprises. The tenant farmers pay annual rents to the landlord, who in this modern age is not an individual but a corporation, the Crown Estate Commissioners. Running the estate is a joint landlord–tenant operation. Permeating this relationship are the rules of the open fields that have evolved across the centuries. Such rules assure the rights of the tenants to their lands, the continuing sequence of crop rotation, and the care and upkeep of the sykes. These rules are enforced by one of the few surviving Courts Leet in England. Meeting each December, the Court Leet (a basic political unit of the village) at Laxton enforces fines levied against tenants who have plowed outside the boundaries of their holdings in the fields or left rocks or trash on the sykes.

A major responsibility of the Court Leet each year is to swear in the twelve members of the field jury who annually inspect the open field sown in winter wheat. Beginning early on an autumn morning, all twelve members walk along the entire open field, inspecting the boundaries of the strips and sykes.

Edmund Rose is bailiff for the village and is responsible for convening the Court Leet, organizing the field jury, collecting fines, and enforcing the rules of the open fields. His father held the office before him. Today Edmund Rose is just one tenant farmer, but in the sixteenth and seventeenth centuries his ancestors (by the name of Roos) were lords of the manor and owned the entire estate. So Rose's roots run deep into Laxton's past. As he approaches retirement, Rose wonders how long Laxton will last in its race against a post-industrial age. His love for the village is plain when he says:

It's not one of the most economic ways, but it's our little part of England. And we are proud to uphold the traditions that our fathers upheld for us. And given the good will of the landlord to us as tenants, we can see our children continuing it.

Laxton's medieval ways do not extend beyond its open-field system of agriculture. Farmers use modern machinery, such as this combine.

Robert Holmes

Because a farmer's holdings are not contiguous, he must move his tractor and machinery from strip to strip, a time-consuming method of working the land.
Robert Holmes

Why does Laxton survive? Why did it not go the way of all other English villages in the East Midlands? Answers to this searching question come in geographical, sociological, and economic categories.

First, the geographical. There is the isolation of the village—it is clearly off the beaten track, lying midway between two major highways that run north and south in England—the A-1 and A-614. Even today the primary interest of the villages between these two trafficways is agriculture, and the landholding pattern at Laxton has continued to serve the interests of its residents.

What is more, for Laxton and the villages that surround it, enclosure came late compared with the rest of England. When it did come, new drainage schemes often had to be devised at a heavy cost to the owners. At Laxton today we can see the way strips were laid out in harmony with the natural fall of the land. Those areas that were poorly drained through the centuries are the sykes of the fields today. To have changed the contour of the land in the mid-nineteenth century would have come at a substantial price to the new owners.

Sociologically, tradition has a firm grip on Laxton, as Edmund Rose has indicated. Tradition, as defined by the Ger-

Below: The view from the church tower shows the road that leads from the village out to the West and Mill fields. At right, cattle graze on private property. Many farmers augment their income by cattle rearing or by dairy farming, activities that allow them the luxury of continuing a method of farming that is not cost effective.

Both photographs by Robert Holmes

man sociologist Max Weber, is "everyday routine as an inviolable norm of conduct." For the farm families at Laxton, conceiving of the open fields as converted to compact blocks of land or as one great, corporate farm is next to impossible. The community spirit they enjoy is part of their tradition, and the grouping of their homes in the village encourages that spirit. Simultaneous activity—all plowing at the same time, all sowing at the same time, all harvesting at the same time—contributes to community spirit as well. Furthermore, there is a rare intimacy with the land. Even though there are no markers, the farmers know the boundaries of their strips as well as they know the backs of their hands. Bill Haigh tells a newcomer:

> I could take you onto the Mill Field, and it would all look alike to you. But I could point out where all the boundaries are to within a yard.

In many ways their lands are extensions of their very selves.

Finally, there are economic reasons for Laxton's survival. In terms of the larger economies of scale, there is little, if anything, cost effective about Laxton's agricultural system in its present form. Estimates project that farmers would earn up to 20 percent more with normal, contiguous fields. But most have other agricultural projects in addition to their land in the open fields—projects such as cattle rearing or dairy farming. When all these enterprises are put together, a modest livelihood becomes possible. No one is getting rich from the system, but survival is possible in a way of life that is all Laxton farmers have ever known.

What about the future of Laxton? It is no secret that from 1952 to 1981 Laxton had a most sympathetic owner and landlord: the Ministry of Agriculture. While tenants paid rents to the ministry, there was a continuous backlog of repairs, the cost of which was not offset by the rents. It was costing the Conservative government of Prime Minister Margaret Thatcher $30,000 a year to maintain the village's forty houses and farm buildings. As a result, the village and open fields were put up for sale by the government.

No one anticipated the public outcry that resulted. Conservation groups, academic experts, and even unions protested the relinquishing of England's last open-field village. Joan Thirsk, an economic historian at Oxford, likened the selling of Laxton to the dismantling of Stonehenge for the building materials it contains. So the ministry sought a buyer who could be relied upon to do nothing to jeopardize the open-field system of farming. In May of 1981 such a buyer came forward in the form of the Crown Estates Commissioners, a complex department that administers the property owned by Queen Elizabeth personally and not by right of being the sovereign. Revenue produced by the Crown Estates is subsequently turned over to the government in exchange for the support of the royal family. It is a strange and ironic mixture of aristocratic/bureaucratic landholding that will determine the future of Laxton.

If the commissioners' record since their purchase of Laxton is any indication, the village's immediate future appears bright. Rents were raised according to schedule a year and a half ago, but only after assessing the extent to which Laxton's farm families had maintained and improved their holdings. Drainage projects are under way in the fields, and the farmers are taking part in each stage of the process. Adding to the village's present optimism have been bumper wheat crops in 1982 and 1983. The 1984 crop, which was still in the South Field at this writing, looked equally promising.

The big fear, of course, has been that over time the commissioners would discontinue the open-field system and join the strips into one large farm. Just the opposite has been the case. When one farmer died not long ago, his strips were redistributed among other farmers, but only with great care so as not to violate the centuries-old rule that no two separate strips in the fields would be joined by a farmer's acquiring a third strip.

The key to survival for this village that won't let go of the Middle Ages lies in the ability of its farmers to adapt to changing circumstances. A kind of pragmatism governs Laxton farmers in that process of adaptation. Ernest Kent, who took up Ide Farm in the 1950s, summed up the new relationship between landlord and tenant when he said recently, "They've got us, and we've got them. So we'd just as well work together to make the best of it." That same pragmatism joins with a sense of history among Laxton farmers to perpetuate what they consider to be the native values of rural life. □

Knockouts in the Nest

Sibling rivalry can have fatal consequences for great egret chicks

by Douglas W. Mock

The egret chick was under attack. Its nape was nearly bald from days of repeated assaults by its two older siblings, and the back of its head oozed blood. Now flailing its quilled wing stubs for extra support, the young egret pumped its gangly legs, seeking new toe grips in the branches of a bush just outside the nest. It took another sharp blow to its neck and moved faster as an older sibling followed it over the rim of the nest.

Usually, the older egret chicks, one and two days senior to the chick under attack, abandoned their assaults when the younger chick fled the nest, but this time things were different. With a loud squawk, one senior landed a dozen solid shots on the junior's skull, causing it to plunge forward once more. Losing the grip of one foot on the main bush limb, the victim reached out futilely with the toes of its other foot. It fell eighteen inches and dangled upside down, low in the bush. Although there was dry grass just three feet below, the fall would probably mean death for the bird, either quickly from predators or slowly from exposure and parental neglect. (Parent egrets seldom tend their offspring outside the nest.) Three days without food (because of attacks by its older siblings) had left the chick weak and dehydrated. Nonetheless, it thrashed and swayed frantically for a few minutes. At last it let go, dropped to the ground, and lay motionless but still alive. By the following dawn, it would be taken by a predator.

Seventy-five feet away, I watched the drama unfold and dictated the events softly into a tape recorder. My assistants and I had seen such struggles before and would see them again in the next few summers. By rotating observers in our large plywood blind in the center of this egret colony, we had maintained a constant vigil over this nest—and fourteen others—for several hot and sticky weeks. We had come to Port Lavaca, Texas, on the Gulf of Mexico, for four months of each year from 1979 to 1982 to study siblicide—the killing of a sibling—certainly one of the most extreme forms of selfish social behavior.

The theoretical importance of siblicide is linked to W.D. Hamilton's concept of

A pair of great egrets exchange nest attendance duties.

Jeff Foott

Douglas W. Mock

A great egret chick that is only one or two days older than its sibling may intimidate, attack, or even kill a younger nest mate in the vicious competition for food. In this sibling fight, the older (and taller) chick has landed a blow that snaps its opponent's head backward.

inclusive fitness, which depicts evolutionary success (total genetic contribution to future generations) as a combination of the individual's own lifetime reproductive success plus specifiable fractions of that achieved by its kin. This second avenue, the indirect component, has generated much of the sociobiological excitement of recent years because it offered a means of evolving altruism and cooperation via what has come to be called kin selection. This logic might look at two vertebrate brothers, for example, and note that an average of 50 percent of their genes are identical through common parentage: a nepotistic favor by one would thus reward the performer's own genes, albeit indirectly.

Relatively little attention has been paid to the flip side of that logic, that the half-full glass of water is also half-empty. Because the individual always carries twice as many of its own genes as it shares with even a full sibling, there must be occasions when nepotism takes a back seat to self-preservation. That form of selfish behavior is what I wanted to study. I wanted to learn why spectacular and destructive actions had evolved in ardeids—the family of long-legged wading birds that incorporates egrets, herons, and bitterns—and what ecological factors influence such behavior today.

Ardeids typically lay more eggs than can survive, and unlike most songbirds, they don't hatch their eggs simultaneously but at one- to three-day intervals. Because incubation starts while laying is still under way, the chicks hatching from the earlier-laid eggs have a substantial head start in development, often possessing an insuperable advantage over their siblings.

In the 1940s, British ornithologist David Lack proposed that such a pattern of incubation and hatching enables the female parent to hedge her bets. She must commit herself to a specific number of eggs early in the spring, yet she cannot know whether there will be enough food when the chicks' need for nourishment peaks several weeks later. If the season turns out to be rich in food, all nestlings may fledge; but if it is poor, the younger chicks are likely to starve first, thereby enabling parents to raise the maximum number of healthy offspring in spite of an unpredictable environment. Such brood reduction is a lethal game of musical chairs—one in which the first-hatched players usually have substantial advantages of size, strength, and coordination.

The role that overt aggression might play in such situations has not been well understood, despite the many recorded anecdotes of sibling fights among nest mates. In a few eagle species, for example, one chick invariably kills its only sibling. But most of those species nest in such isolation that it is difficult to undertake quantitative field studies. Our 1979 discovery that great egrets in Texas often kill their nest mates provided a good opportunity to make just such a study. We hoped that what we learned about these egrets would prove generally applicable to other, less accessible species. We decided to compare great egrets, which we knew often killed their siblings, with neighboring great blue herons, which, it seemed, did not.

Our method was to keep a vigil over wild broods, recording everything pertaining to aggression and the distribution of food. Because both these bird species nest in the same colonies and the relevant events occur only sporadically, we could keep accurate records on as many as fifteen nests at once throughout the first month after hatching. Team members rotated in and out of the blind in twenty-four-hour shifts and were replaced quickly during the colonies' quietest mid-afternoon period. Thus an observer would enter the blind at 3:00 P.M., record until 9:00 P.M., sleep until 6:00 A.M., record until 3:00 P.M., and then return to a rented house on the nearby mainland.

To supplement this detailed information, we also visited hundreds of nests in other nearby bird colonies in Lavaca Bay, stopping at each nest for only a few seconds every fourth day to see how the dye-marked nestlings were faring. To document the effect of sibling aggression on growth, we took standard size and weight measurements at sixteen egret nests. In the first year of the study, we also hand-raised six broods of captive egrets in a crude aviary—chicken wire wrapped

around the support poles of our rented stilt house. We studied growth and development in this group, an exercise that provided us with a provocative and serendipitous clue to the puzzle of siblicide.

Sibling aggression is an important aspect of survival in great egret broods. The members of all observed nests repeatedly fought hard throughout the first month, with the larger siblings generally initiating the attacks and almost always winning. In three-chick nests, for example, brood mates fought an average of 109 times during the first twenty-five days after hatching. Deaths caused by siblings were common and affected the youngest and smallest disproportionately. The older, larger chicks typically dominated and acquired more than their share of available food, initially by being stronger and faster, later by intercepting the food supply. This advantage inexorably worsened the runts' survival chances. About half of the youngest nestlings died in the first month, and most of those deaths were apparently hastened by the senior chicks.

To our surprise, aggression did not decline when food was abundant. The six captive broods, which we fed three times a day (providing considerably more food than parents do), continued to fight. Two wild broods, given food bonuses every day, also fought viciously. Sibling aggression seemed to be relatively inflexible, though eventual survival of the youngest egret chick may be determined by the total amount of food received. If the parents manage to deliver lots of fish, the youngest chick may get enough food to withstand the beatings it gets.

The great blue heron chicks were far less aggressive than the egret nestlings. Many broods never even had one fight, and sibling aggression almost never seemed to contribute to fatalities. When the youngest heron chicks died, the cause was generally slow starvation.

In observing the feeding behavior of egrets and herons, we were looking for clues to explain the differences in aggression between the two species. Great egret parents in Lavaca Bay typically feed on very small fish—menhaden and silversides—with an average length of two

Joni James

Small fish—weighing a fraction of an ounce each—are typical prey for great egrets, below. During the first week, when the egret parents deliver this food to the nest floor, all siblings in the clutch have a chance to scramble for a meal. Later, the feeding methods shift, and aggression becomes a key to monopolizing food. In Texas, great blue herons, right, catch relatively large fish—more than one hundred times the weight of egret prey. Perhaps because fighting doesn't help them monopolize such huge food items, Texas heron chicks are less aggressive than their egret counterparts.

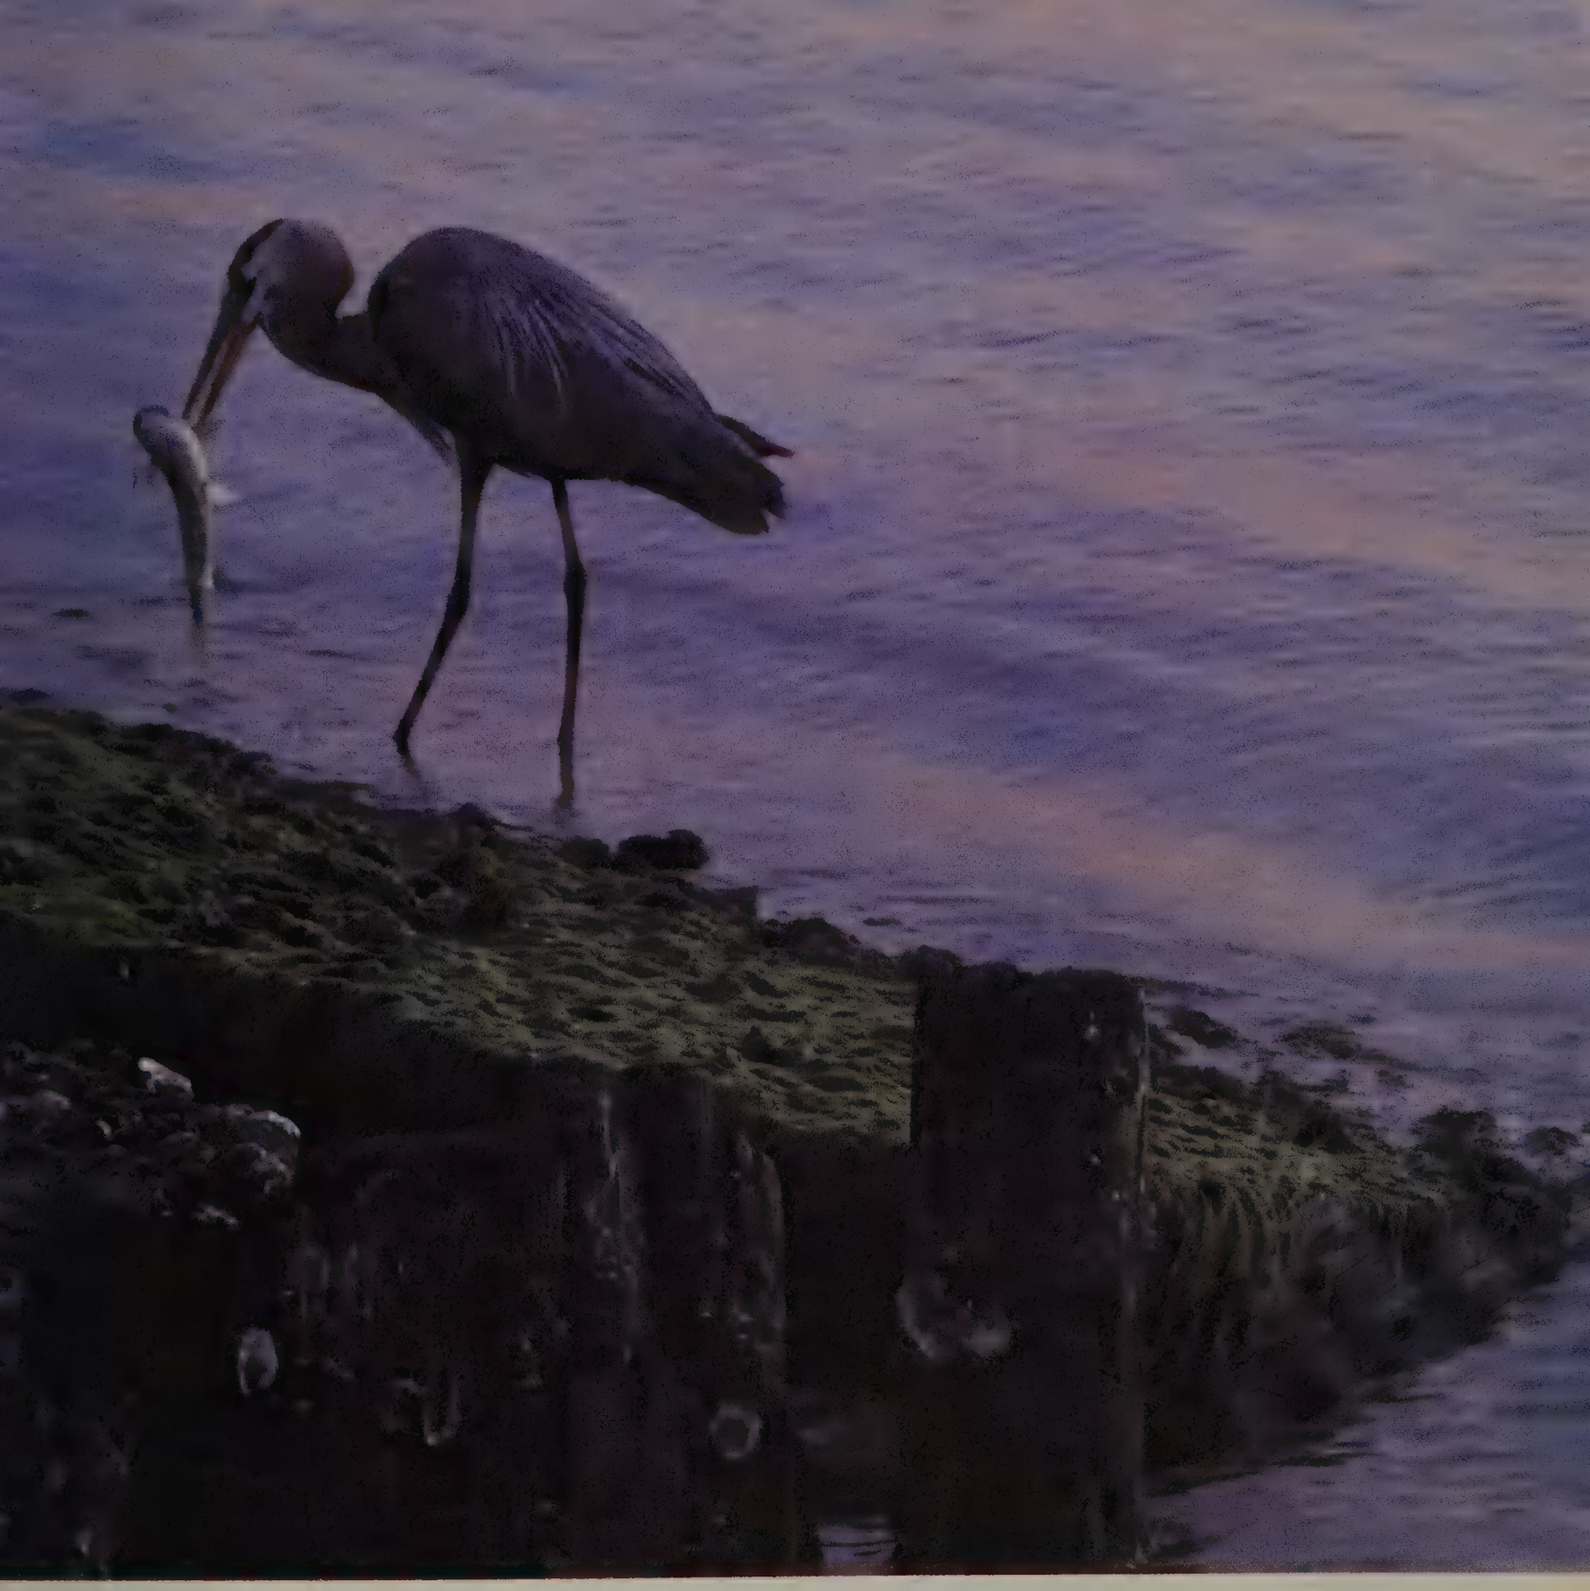
Brian Milne; Valan Photos

inches and weight of only 0.07 ounces. They capture and swallow many of these fish in the shallow marshes around the bay, then fly back to the nest, where they present the food to the chicks as regurgitated boluses (tidy little wads of whole fish held together with saliva). During the first days after hatching, parent egrets regurgitate the boluses onto the nest floor, and the chicks race to grab them. Such feeding contests, which ecologists call scramble competitions, put a premium on speed. The egret nestlings quickly acquire skill in this competition; the mean time for grabbing a bolus drops sharply from about six seconds at hatching to about one second by ten days of age. So steep is this curve that even a one-day difference in age can result in as much as a 31 percent reduction in time, which means roughly one-third more food consumed if the supply is small. Older nestlings thus gain a feeding dividend from their age advantage. Even though the nestlings have already begun to fight, relatively few of the youngest chicks are so intimidated that they miss any meals during this early phase of their development.

When egret chicks are nine days old, however, their behavior changes radically. At that age, they alter the nature of their food competition. Senior chicks begin to intercept the boluses before they reach the nest floor. Now the chick scissors the parent's bill with its own. Then, sliding its bill up and rolling it under the open corner of the parent's mouth, it catches the bolus as it falls out. This technique enables one chick to monopolize the whole bolus before it lands on the nest floor.

The contests for food, accordingly, shift from gobbling food off the nest floor to jockeying for a position in front of the parent. At this point, any junior nestling that can be intimidated to even a slight degree can be excluded effectively from the food. Now boluses are more likely to be acquired and kept through aggression. The siblings continue to fight, and the already established dominance of senior over junior is maintained. And because parents bring an average of only two and a half boluses per feed (either this is all they can catch or they keep some for themselves), the share of food going to the oldest nestlings grows while the share going to the youngest dwindles.

By contrast, great blue heron parents provide their young with another sort of prey. They feed their chicks huge fish, mostly mullets, about five times longer and one hundred times heavier than the prey of egrets. After one of these fish is regurgitated onto the nest floor, heron chicks peck at the softened front end, which has been partly predigested by acids in the parent's stomach. No heron nestling can monopolize these meals because—for several weeks at least—it is incapable of hefting and swallowing such large fish. Accordingly, intimidation among the siblings is less effective. After the chicks have chiseled off the softened tissue, the attending parent reswallows whatever remains of the fish. The fish is again "cooked" in the parent's stomach acids for another half hour or so, then regurgitated once more. This process may be repeated three or four times—during which the fish shrinks like a bar of soap in the shower—until the last of the tail can be gulped down whole.



These observations led me to suspect that the size—and perhaps not the amount—of the food offered to newborn chicks might be an important key to the intense sibling aggression seen among some nestling birds. According to the literature on other siblicidal bird species, food size does indeed correlate with highly aggressive nestling behavior across a broad range of birds. Young eagles, owls, ospreys, and skuas are fed on small bits of food torn by the parents from large prey before presentation. Young pelicans, kittiwakes, and boobies take either small or predigested food directly from the parent's mouth. These birds are also siblicidal. In oystercatchers and grebes, where sibling aggression but not siblicide is known, food is likewise small enough to be monopolized.

In the spring of 1982 another team and I returned to Lavaca Bay to test the prey-size hypothesis with both egrets and herons. If large prey really do promote pacifism in great blue herons while small prey promote siblicidal aggression in great egrets, what would happen if each species were reared on the opposite type of diet by foster parents? We knew that these birds, like many species that nest in colonies, cannot recognize their young until several days after hatching. In 1981, a pilot study on one nest had shown that egret parents accepted a heron brood readily.

To carry out the experiments, we moved ten three- or four-egg heron clutches to egret nests and vice versa. We then observed the feeding and fighting in all the nests, which we compared with data previously recorded for normal broods. To eliminate possible complications from the fact that heron chicks ordinarily receive greater amounts of food from their natural parents than they would from the foster egret parents, we gave four of the heron broods a daily bonus of small fish, equal to about 30 percent of the foster parents' delivery. (It turned out that this, like the supplements we had given to egret chicks, had no measurable effect on aggression.)

The results of the experiment were dramatic. The heron chicks raised by foster egret parents on tiny units of food fought

In a field experiment, egret chicks were raised by great blue herons. Below: An egret chick persists in its vigorous attempts to intercept a food delivery, although the fish brought by its heron foster parent is too large for it to swallow. As the adult tries to reswallow the fish for further digestion, the chick hangs onto the tail of its potential meal.

Douglas W. Mock

from the start. Furthermore, they quickly acquired the habit of scissoring the "parent's" bill and taking the boluses directly. As in the natural egret broods, the growth of the youngest cross-fostered heron chicks fell behind when they were competing for the indirect feeds. After the switch to direct feeds, these chicks were effectively intimidated. By the twenty-fifth day, eight junior heron chicks were dead, six as the victims of siblicide. (The youngest chick in one brood was still alive and one had failed to hatch.)

The second part of the experiment was more puzzling. The young egrets that received large-sized food in the heron nests also fought quite a bit and tried to feed by scissoring the herons' bills after a week and a half or so. These attempts were catastrophic: A young egret trying to scissor a heron's bill during the passage of a partly digested fish was often pinned to the nest beneath a gargantuan mullet and matted with fish mucus and heron saliva. The fostered egrets remained thin and weak and many seemed incapable of knocking much food off the proffered fish. Seven of the egret chicks died. Because aggression had continued and presumably contributed to their deaths, they too were counted as victims of siblicide.

It would therefore seem that great blue herons show flexibility in developing aggression against their siblings and that this behavior can be elicited by the size of the food. But the interpretation of the behavior of egret chicks is not yet clear. Although they do not always kill their junior siblings, they seem to be less flexible in terms of their intra-nest fighting. I can offer several possible explanations for why more flexibility evolved in herons than in great egrets. Perhaps the bay in Port Lavaca, where we did our field research, offers two general sizes of fish, tiny and huge, and the egret adults are too small to exploit a supply of giant fish. Certainly, egret chicks seem too weak to carve off sufficient food from large carcasses.

Another explanation might be that both great egrets and great blue herons inhabit a wide geographic range. Great egrets live throughout the tropics; great blue herons are found across most of North America. Perhaps populations of both species that live in areas where small fish predominate are commonly as siblicidal as the Texas egrets. Perhaps parents in habitats that have both large and small prey can influence sibling conflict by their choice of food. Despite all the research, one provocative question lurks in the background: Why don't parents of siblicidal ardeid chicks intervene and stop the mayhem? □

After nine days of life, great egret chicks no longer scramble for food on the nest floor. Competition and aggression intensify as nestlings start to take food directly from the parent's bill.

How to Select, Climb, and Eat a Tree

essons from the porcupine school of forestry

y Uldis Roze

In a forest on a clear summer night, one n sometimes hear a sound like soft rain lling. But the light drumming on leaves not caused by raindrops; it is the sound caterpillar droppings tumbling down rough the canopy. Human ears cannot ck up the noises caterpillars make when ey feed—the tiny gnashings of caterpil- jaws, the scratchings of caterpillar feet er leaves.

When I am in the forest and imagine ch things, I also imagine other sounds—chorus of *ptuis!* and groans, as disgusted terpillars spit out foul-tasting leaves at they've chewed a minute too long. For ees have weapons against the caterpillar, isonous or unpalatable food additives, digestible structural materials, and poor trient packages. The forest is a tough ace for an animal to find a meal. The earest evidence of this is the small nount of living biomass consumed by rest animals every year.

One animal that manages to make a ccessful living in the forest is the North merican porcupine, *Erethizon dorsa- m,* which has physical as well as behav- ral adaptations that permit it to live its e as a tree feeder. In my seven years of udying porcupines in the Catskill Moun- ins of New York State, I have found em to be a good match for the overlap- ng and often subtle defenses erected ainst them by the trees.

Like all of North America's human ock, the porcupine is an immigrant. It rived on this continent fairly recently, th the final establishment of the Pan- na land bridge some two million years go. Its closest relatives are Central and outh American porcupines of the genus *oendou.* These animals are so highly lapted to life in trees that they are sel- om observed on the ground; conse- ently, very little is known of their natu- l history. It is this arboreal heritage that *Erethizon* brought with it to the new continent.

Although the North American porcupine can walk considerable distances on the ground, it is at its best in a tree; seeing it up there you realize what an agile and coordinated branch walker it is. How does a short-limbed, quilled animal like a porcupine get into a tree in the first place? Its method reminds me a little bit of a telephone company linesman. The porcupine sinks its claws into the bark and scales the tree straight up, moving deliberately and testing its hold at every level. The animals prefer rough-barked trees, whose crevices offer a nice fit for the claws. They use certain trees over and over as resting spots; the bark of these trees takes on a scuffed, abraded quality.

The tail, a powerful and versatile appendage, also helps in climbing. Its underside is covered not with quills but with stiff bristles that point down. These are set in thick connective tissue. Like a woodpecker, the porcupine uses its tail to check backward sliding, pressing it hard against the trunk of a tree. In effect, the tail is a fifth leg that the porcupine can use for climbing and descending; but it lacks the prehensile properties of a monkey's tail or the tails of South American porcupines.

Porcupines prefer trees with rough bark, but they are perfectly competent at climbing smooth trunks as well. To do so, the animals turn their large, naked footpads inward and grip the trunk through frictional force alone. Tuberosities on the footpads help them do this. Porcupines have powerful clenching muscles in their thighs, and they can press their footpads so firmly against a small trunk that an individual animal can hold on without using its forelimbs. Males tend to have larger footpads than females, possibly because they are generally heavier.

Up in the canopy, the porcupine moves confidently from branch to branch, sensing the substrate and conforming to it with its footpads. One can seldom observe the animal in this element, however, because it is almost always a nocturnal feeder and remains hidden in the foliage.

I watched one porcupine feeding in the canopy on a May night in 1983. The animal had climbed into a young beech tree whose leaves had so recently opened that the tree seemed transparent. I could see the animal well—a full moon threw the porcupine's round shape into dark relief. It moved ceaselessly through the branches, harvesting the nutritious leaves. Sometimes the body hunched into a tight ball; sometimes it stretched out into a vertical clinging mass, then moved out again toward the tip of a branch. A brisk wind was tossing the branches, carrying the porcupine in heavy arcs through the sky. Yet the animal never stopped feeding; at times it seemed to reach impossibly far to snag neighboring branches and bring them into feeding range. Over the modulations of the wind, I could hear the faint sounds of leaf crunching from the dark rider above me.

Beech trees have tough, almost unbreakable, branches, but other tree species on the porcupine menu are not so hardy. Aspens, for example, crowd their most nutritious leaves at the tips of branches that are too thin and brittle to carry the weight of a seventeen-pound animal. The porcupine seems to have a good idea of the difference between a modest risk and sheer folly, however. To harvest terminal leaves, the animal invokes the elegant technique of "nip twigging." This method is simple: From a safe perch, the porcupine gnaws off the end part of the branch, then holds it in its paws and consumes the leaves in safety. The bare twig is thrown away.

Porcupines may be savvy at judging what a limb will put up with, but perhaps

Uldis Roze

In winter, porcupines eat mainly tree bark, and sometimes they are extremely picky about which trees they eat. At right, a lone beech tree in the Catskill Mountains of New York has been stripped of all its bark, while others around it have not been touched. In early spring, porcupines abandon the bark, which is not very nourishing, and move on to greener parts—the catkins of quaking aspen and the leaves of sugar maple, beech, and white ash. The porcupine below is drowsing in an aspen in April.

John Shaw

inevitably, there are miscalculations. The animals can and do fall out of trees, though the result is rarely fatal. Perhaps the most compelling evidence for this comes from an examination of animal skeletons taken from the wild. When I examined fifteen adult skeletons in two museum collections, nine showed evidence of healed fractures. Five juveniles showed no evidence of injury; perhaps they fall less often because their lighter weight puts less strain on a branch and their periods of exposure have been shorter. The commonest injuries I saw were broken ribs, but I also found a broken hip, a broken tibia and fibula, and breaks in a sacrum and a humerus. In all cases, the bones had healed.

Broken bones may represent only a small fraction of the injuries, though. Animals falling into snow or through low branches may not hurt themselves. Yet in all such falls, you might think a porcupine risks impaling itself on its own quills. One of the more surprising findings of my work has been that the animals have developed a mechanism to protect themselves from just such a calamity. The quills, I have found, contain an antibiotic.

I discovered this after a work-related mishap in September 1983. I was trying to capture a powerful male that I had followed up into a tree when the animal drove a quill deep into my upper arm. To my horror, the entire quill disappeared under the skin. Over the next two days, it traveled downward through tissues in my arm and elbow, causing me intense pain at times. Then, while I was teaching a class, I felt a scratching inside the arm of my shirt. The quill had emerged from my lower forearm completely intact. What I found remarkable was that for the entire course of its travel it had started no hint of an infection. I mentioned this story to Ward Stone, chief wildlife pathologist of New York State, and he suggested looking for antibiotic activity on the quills.

This suggestion turned out to be apt. When I made an extract of porcupine quills and tested it against bacteria, the extract slowed bacterial growth. The antibiotic has not been chemically characterized, but it appears to be a novel fatty acid. As expected of a fatty acid, its antibiotic activity is relatively mild. What this means is that porcupines carry a medical insurance policy against their own most formidable weapon, their quills.

Getting up into a tree and staying there is just the first step in finding food. The porcupine must be able to eat, digest, and metabolize the tree products it gathers. Here the evolutionary battle between the trees and the herbivores escalates. The

porcupine approaches tree feeding with impressive structural tools.

Winter feeding for porcupines means bark feeding; tree bark is their main source of sustenance, and it's not a tender dish. When feeding on beech and sugar maple, the porcupine must shave thick bark twice. The first pass removes the dead outer layer, and the fragments are allowed to fall in the snow below. A second pass shaves off the living inner bark; the porcupine grinds this up with its cheek teeth and swallows it as a fine purée. All of this involves a good deal of noisy chewing; but a porcupine's rootless incisors, hardened by orange iron salts, cannot be worn down by an entire winter of bark feeding.

Extracting nutrients from the chewed bark is facilitated by a body that is dedicated to digestion—about 75 percent of the porcupine body cavity is taken up by stomach, caecum, and intestines. The caecum is a large sac, filled with microorganisms, that resembles the rumen of ruminant herbivores. It converts otherwise indigestible carbohydrates into metabolizable fatty acids and contributes significantly toward total energy requirements.

But in spite of this large and efficient digestive system, the animal loses weight during the winter. The inner bark of trees contains a very low concentration of nitrogen (needed to build proteins) and an excess of indigestible roughage. The roughage limits the rate at which food can be processed, so porcupines can't compensate for the low nitrogen content of their food by eating more. Though their digestive tracts are always full, the animals are physiologically starving.

For example, during the winter of 1983–84, the porcupines in my study population lost an average of 17 percent of their body weight. One male had lost this much by mid-February. It became listless and unresponsive, allowing me to practically touch it before it erected its quills. Over the next two weeks, this animal lost an additional 17 percent of its weight. I found it frozen to death on March 3. Yet an autopsy showed that its digestive tract had been full.

Porcupines cope with the dietary stresses of winter by reducing their diet

Some trees on the porcupine diet crowd their best leaves at the tips of branches. To harvest this elusive crop, the porcupine chews off the part of the branch that is too delicate to hold its weight. It then takes this piece in its paws and leisurely eats the leaves. This "nip twig," such as the bare linden twig below, is then thrown away.

Uldis Roze

breadth and minimizing their movements. Each animal feeds on only one or two species at a time, while the total population feeds on eight to ten different species. The narrower diet may include the one or two tree species most easily digested by a given animal's microorganisms. When an animal is starving, even a slight increase in digestive efficiency may spell the difference between demise and survival.

Another strategy is to select winter foraging areas where preferred trees are abundant. By doing so, porcupines reduce travel time and exertion in the snow. In deep snow, the animals end up dragging their bellies since they can't get firm footing; this creates feeding trails that look like the work of giant centipedes. Porcupines have other tactics for minimizing snow travel: They move back and forth in their own footsteps and travel in the shelter of rock overhangs. But most important, they move less: Their winter ranges in the Catskills average only 12 percent of their summer ranges.

As the winter snows melt in April and May and spring peepers begin calling in the dusk, porcupines burst out of their dens. Trees begin pouring nutrients into emerging leaves, and porcupines quickly abandon the bark for this incomparably richer diet. Whereas tree bark averages only 2 to 3 percent crude protein, spring foliage may contain more than 20 percent on a dry-weight basis—richer than the "enriched" cereals available to humans.

That it is the high protein content of young leaves and buds that attracts porcupines is suggested by their feeding methods. Their discarded nip twigs show they feed on the leaf blades alone, rejecting petioles and branch tips. Nitrogen analyses of the leaf blades show that protein levels are three to five times higher than those of the petioles. In early spring, porcupines are similarly choosy in bud feeding. Individual buds are neatly excised (crude protein in excess of 20 percent); terminal twigs are discarded (crude protein 7 to 9 percent). At this time they forage on sugar maple (buds and leaves), beech and white ash (leaves only), and the catkins of quaking aspen.

However, the trees are rallying to defend themselves. As spring eases into summer, the trees accumulate tannins in their leaves, polyphenolic compounds that alter proteins and inhibit the porcupines' digestive processes. And by mid-June, the porcupines have once again moved on to a new diet, this time the tree species that will last them till leaf drop. Most important of these are American linden (*Tilia americana*), quaking aspen (*Populus tremuloides*), and bigtooth aspen (*Populus grandidentata*). As in the spring, they select only the most protein-rich portions of the new fare, rejecting petioles and twig tips. The crude protein content of all the trees declines through the summer, dropping to less than half of the spring values. This forces the porcupines to absorb more bulk during feeding, yet they continue to gain weight.

Trees have a second, very effective defense against leaf-feeding porcupines. They carry a horribly unbalanced load of sodium and potassium ions. In the porcupine body, these minerals are found in roughly equal ratios. But the summer vegetation threatens the balance, because it has a potassium–sodium ratio in the range of three hundred to one or higher. The porcupine needs the sodium, but it can't hold onto it because its kidneys cannot get rid of the flood of potassium without giving up some sodium as well. The animal must either stop eating green vegetation or find a sodium supplement.

All strict herbivores face this problem, but in the Catskill Mountains, natural supplies of sodium are scarce, and human salt artifacts have a near-fatal hold on porcupines. I have found porcupines traveling almost a mile from deep woods to a farm building, where they spent much of the night chewing on wood laced with sodium chloride. Others traveled to roadsides, looking for traces of salt put down by road crews the previous winter.

During the summers of 1983 and 1984, 59 percent of my study animals were driven out of the forest and to human settlements by their need for sodium. If only adults are considered, the figure jumps to 71 percent. Since the sodium-seeking behavior coincides with the period when porcupines are feeding on greens, I consider it a toll exacted by plants from their herbivore predators.

This toll falls most heavily on lactating females. Infants were never observed chewing salt. Chewing on a building or licking a roadside are unquestionably the two most life-threatening situations a porcupine can find itself in. This suggests that whether a porcupine is killed directly by an angry homeowner or randomly by a

A porcupine absorbs itself in an apple. Porcupines in the Catskill Mountains of New York are partial to apples, especially bland, mealy ones with a low level of organic acid. Trees with higher acid levels could be warding off herbivores.

Leonard Lee Rue III; Bruce Coleman Inc.

speeding car, the probable result is an orphan left in the woods.

The interesting thing about the summer food eaten by the porcupines is that it is extremely rare in my forest study area. Only nine trees out of a thousand are lindens, one out of a thousand is a quaking aspen, and fewer than one out of a thousand a bigtooth aspen. Yet the porcupines travel unerringly in the night to climb a tree of the correct species and feed on it.

The aspens are pioneer species. But once a forest matures, their seedlings can't compete with the climax vegetation of beech, maple, ash, and oak, and the aspen is eliminated. This can't explain the scarcity of the linden, however. I believe this tree may be a fugitive species, which hides from herbivores by keeping scattered. To keep in touch with each other genetically, the lindens produce fragrant flowers that attract bees, thus insuring cross-pollination at a distance.

The loyalty of porcupines to these rare trees intrigued me, but I never suspected how far the animals had taken this loyalty until I began radio tagging them. As I followed my radio-tagged animals, I routinely marked their feeding trees. Frequently, after struggling at night along treacherous terrain, I would locate a porcupine in a linden or an aspen. As I walked around the tree, I would often find my own tiny plastic marker nailed to the bark. Often the animal had been there weeks or months before. In other words, porcupines were recognizing not only a rare desired species; they were picking out specific trees out of hundreds of thousands in their home range. But why?

During the summer of 1984, I selected thirteen linden trees widely spaced in the forest and examined each tree once a week for signs of feeding. Here, the nip twigging behavior of the porcupine became a valuable experimental aid. Even a single petiole-spurred twig can be found by searching under a feeding tree. By comparison, one would have to be tremendously lucky to find the single bite taken out of an accessible tree by a deer.

The results were startling. At the end of the summer, two trees out of the thirteen under surveillance had accounted for 90 percent of all porcupine feeding. Often, after a week's absence, I would carry away armfuls of nip twigs to clear the ground for future observations. The two trees had no more leaf protein than the others. But there was something clearly different about them—their leaves contained only a third as much organic acid as the rejected trees.

I was led to this discovery partially because I had noticed my porcupines avoiding acid in two other circumstances. In addition to tree foliage, a major summer food of the Catskills porcupines is apples. Apple trees do not grow in the mature forest; porcupines travel to the old fields and abandoned orchards on the periphery. The porcupines invested much effort in harvesting apples. One mother traveled almost a mile every night from a resting spot on top of a ridge to an orchard at the bottom, then returned before morning.

Up in the trees, the animals cut nip twigs to harvest fruit growing far out on the branches. They ate only the fruit, which was often harvested while still green. And, as with linden feeding, the animals showed strong preferences for some trees. Some apple trees were stripped bare while neighboring trees lay untouched.

One twisted, hollow-trunked tree I know of stands out as a porcupine favorite. The tree grows on the edge of our orchard and produces early maturing, delicate apples. We seldom get to taste the fruit because porcupines come every summer and strip the tree before the seeds have turned brown. Porcupines tend to be solitary animals, foraging and traveling alone. But on one August night in 1983, I found three animals feeding in the same tree, a record that has not been surpassed. Two of the feeders were males, so upset by each other's company that they spent much of the time grunting at one another instead of feeding. The female, more sensibly, was busy harvesting apples.

The apples of four trees chosen by porcupines did not have any more sugar or crude protein content than the apples of rejected trees. But they did differ significantly in acid levels. The rejected apples contained eleven times more organic acid than those eaten. To me, the apples preferred by porcupines had a bland and mealy taste.

A third acid-avoidance behavior in porcupines cropped up while I was studying salt drive in the animal. To determine what specific salts the animals seek, I built a low cabin and situated it on a porcupine trail. Under the shelter of broad eaves, I attached 180 pickets of wood impregnated with a variety of salt solutions and

Lynn Rogers

The Siberian husky below made the mistake of charging the back of a porcupine and got a faceful of quills. The dog shows no sign of infection; porcupine quills contain an antibiotic that inhibits bacterial growth. At right, a female porcupine in Minnesota serves herself a sapling.

D. Cavagnaro; DRK Photo

arranged randomly. Like Hansel and Gretel's candy house in the woods, my salt house signaled to the passerby: Come and chew. Within a week of putting up the cabin, quilled visitors began arriving.

I confirmed that the animals were seeking sodium. But most interestingly, they showed clear preferences among the nonmetal components of the salts. They preferred sodium acetate, borate, bicarbonate, and other sodium salts of weak acids and made less use of sodium chloride, nitrate, and sulfate, all salts of strong acids. In effect, the animals were seeking the most alkaline sodium salts available.

Thus in leaf feeding, apple feeding, and salt seeking, a common behavioral thread was emerging. Porcupines were trying to minimize their acid intake. The presence of the same behavior in such different contexts suggests an underlying physiological imperative. Why should porcupines avoid dietary acid?

The answer must remain speculative at this time. Perhaps the most obvious place to look is the animal's kidney function. Both acid–base regulation and the regulation of sodium–potassium levels are the tasks of the mammalian kidney. As mentioned before, the porcupine's summer diet floods its system with potassium. Work with other animals shows that an acute increase in acid levels in the blood inhibits the kidney's ability to excrete potassium. And if potassium levels are allowed to rise in the blood, there follows an immediate and severe disruption of muscle and nerve functions.

Are trees defending themselves against porcupines by driving up their acid levels? If so, it's a mechanism that has not been described before. It will be interesting to see whether other leaf-feeding herbivores show the same behavior.

Besides tree leaves and fruit, the porcupines have one more important, but unreliable, food source in late summer and fall—the mast crops, which include acorns of red oak and nuts of the beech tree. Acorns and beechnuts have a much higher caloric content than apples, and porcupines feeding on them put on weight rapidly.

The large oak trees offer comfortable sleeping perches, and a porcupine may stay in the same tree for days at this time, feeding by night and sleeping by day. In October 1984, I was trying hard to capture a female whose radio collar battery was nearing the end of its life expectancy. I reached the animal at midnight on a warm, misty night. The animal was in a giant red oak, hidden among persisting leaves. I could hear her movements above me, punctuated by sounds of acorns falling. I lay down on the ground and waited for her to descend.

I dozed off in the warm night and was awakened about 4:00 A.M. by something pounding the ground near me. I sat up, befuddled, and heard a great snort. A large doe had approached, searching for acorns, and had asked me to declare myself. She now rushed back and forth in great confusion, trembling the ground and looking back in my light beam. Only the porcupine above us retained her composure.

Realizing my quarry would not descend, I trudged home for a proper sleep. When I returned at noon the following day, I found the porcupine sleeping just where I had left her, about forty feet up on a large branch. Below her lay nip twigs and loose acorns from the night's feeding.

Mast crops appear irregularly, in a pattern that no herbivore can depend upon. In my study area, for example, both the beechnut and acorn crops failed in 1983. A few scattered acorns were produced; these were stripped clean by mid-September, well before normal acorn drop in October. As a result, porcupines fell back on the apple crop and also fed heavily on linden and aspens.

Conditions were entirely different in 1984. The trees were full of acorns and beechnuts. The porcupines abandoned the apples and concentrated almost exclusively on mast, with leaves as a garnish. The animals were in excellent physical condition by the time winter returned, but it's impossible to predict what will happen this year. That unpredictability, I believe, is another way the trees resist their herbivore predators.

Even if the mast crop fails, my porcupines will adapt. The forest may have an impressive arsenal of weapons and tactics for protecting its resources from these quiet, tenacious predators, but the porcupines have structural and behavioral tools for survival. To my mind, it's an even match. In my years as a follower of porcupines, I have come to regard these animals as superb foresters. They have much to teach, not only about themselves, but about the forest that has sustained them through two million cycles of spring, summer, fall, and winter. □

Inconspicuous among the shrubs of South Africa's Cape region, the cupped, gray-green leaves of a protea plant hide scores of blossoms from birds and flying insects.

Delbert Wiens

Secrets of a Cryptic Flower

The way to a pollinator's heart is sometimes through its sweet tooth

by Delbert Wiens

The Cape region of South Africa is well known in biological circles for the great diversity and beauty of its indigenous flora. But of all the Cape's intriguing plants, proteas reign supreme. These remarkable plants are shrubs or small trees whose flowers—usually borne in large, conspicuous yellow or red heads—are typically pollinated by the protea bird (*Promerops cafer,* also known as the Cape sugar bird). The plant genus *Protea* was named for Proteus, the Greek god who could assume many different forms, and its various species also take some surprising forms. Some are singularly unprepossessing. Their flowering heads are comparatively small, not especially showy, and sometimes even cryptic—that is, hidden deep within the foliage. We now know that these proteas are pollinated, not by birds, but by small terrestrial mammals, mostly rodents.

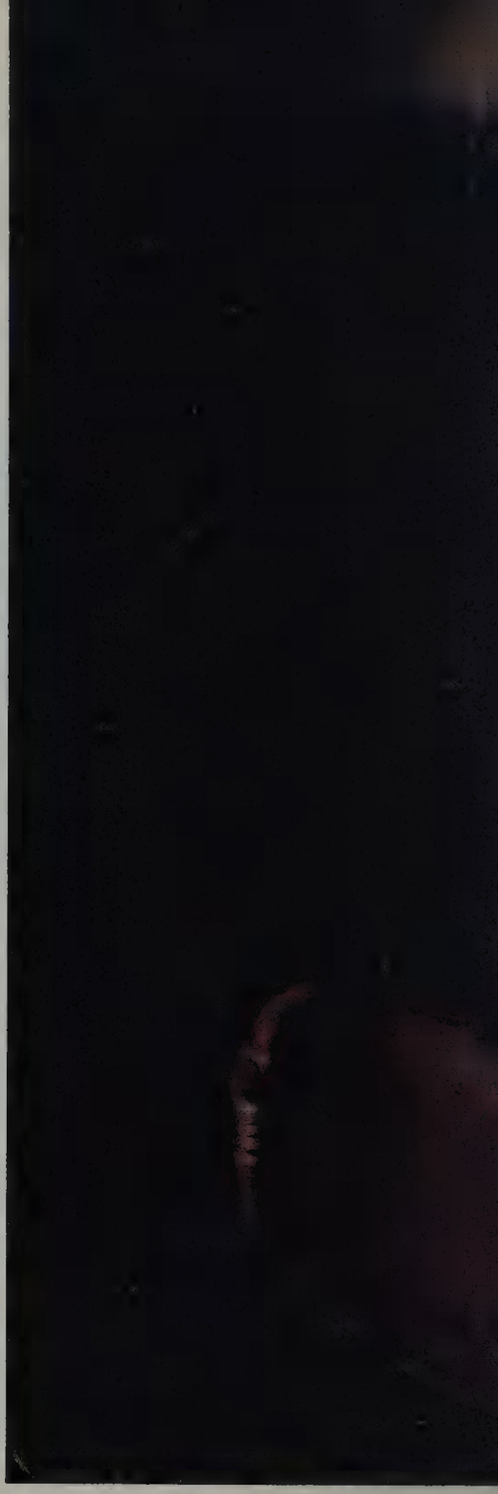
My experience with these plants and their pollinators began in 1972, in Cape Town, South Africa, while I was visiting John Rourke, longtime student of Proteaceae. One evening after dinner, John and I thumbed through one of the many popular books on this plant family. When we came to the photographs of several proteas with cryptic flower heads, he asked me what I thought could possibly pollinate such flowers. I hesitated, for the idea seemed so strange, but finally suggested small mammals. He replied that this was also his guess, as well as that of Knut Faegri, a well-known Norwegian pollination biologist.

Intrigued by this possibility, a few days later we examined several species in the field. A few of the succulent bracts surrounding the heads showed evidence of having been chewed, rodent runways connected individual proteas, and there were even burrows at the base of some plants. The heads secreted copious sweet nectar and produced a yeastlike odor. While these observations supported the possibility of small-mammal pollination, the idea still seemed bizarre. With the exception of bats, I knew of no other mammalian pollinators. Although the Austrian naturalist O. Porsch, looking at Australian plants, suggested the possibility in the 1930s, and

Delbert Wiens

Drawn by sugary nectar, several types of terrestrial mammals visit cryptic proteas. Below, a Namaqua rock mouse visits a ground-flowering protea. Right: Protea flower heads are complex, composed of hundreds of small florets. In this species, the flower head opens slowly from the perimeter, gradually exposing pollen-laden styles to potential pollinators.

J.A.L. Cooke; Oxford Scientific Films



M.K. Morcombe had observed a case of probable rodent pollination in Australia in the 1960s, no quantitative data were available, and certainly no one had given much credence to the idea. We needed unequivocal experimental verification to convince ourselves, let alone others.

Unfortunately, I was on the eve of departure for Australia, and John Rourke was preoccupied with other matters, so the idea was necessarily put aside. He mentioned, however, that he believed there were Australian proteas that strongly resembled those of southern Africa. Several weeks later, in southwestern Australia, I did indeed discover several proteas with floral structures, habits, nectar quantities, and odors strikingly similar to those of the proteas I had observed in southern Africa. Furthermore, the environment of southwestern Australia—with its shrubby, Mediterranean-like vegetation, climate, and soils—strongly resembled that of the Cape region. Could ecological factors in these two distant regions of the earth have somehow promoted pollination by small terrestrial mammals? Again, the situation did not allow detailed studies, but the question was now more intriguing than ever.

Time and circumstance did not permit further investigation of the problem for five years. In the interim Rourke had discovered a study site, approximately sixty miles northeast of Cape Town, on Jonaskop (Jonas head), a mountain in one of the outlying Cape ranges called Riviersonderendberge ("mountains of the river without end," a typically descriptive name so common to the Afrikaans language). Jonaskop reaches an elevation of about

,000 feet (high for the Cape region), but nost importantly, its vegetation was rela-ively undisturbed, access was limited, nd there were well-developed stands of at east nine species of proteas, three of vhich we believed might be pollinated by errestrial mammals.

On Jonaskop I put out a series of live raps in dense stands of *Protea am-plexicaulis* and *P. humiflora*, two species ve believed might be pollinated by small nammals. For several days, I caught a number of such animals, mostly nocturnal odents. One evening, I put a fresh, nectar-ous head of *P. humiflora* into a cage with Namaqua rock mouse. The result was in-tantaneous and dramatic.

The mouse emerged from its sleeping ube (a small, cylindrical cardboard con-ainer), raised its snout in an obvious melling gesture, and then proceeded di-rectly to the protea head (which I had placed out of sight behind the tube). For the next fifteen minutes, the animal inter-mittently lapped nectar from the head; its snout became covered with pollen. Fur-thermore, the structure of the flowering head dictated the animal's feeding behav-ior. Because the styles of the one hundred or more individual flowers that make up a protea head always curve inward, animals attempting to lap nectar must forage from the center of the head outward. The nec-tar reservoirs are located beneath the in-wardly curving style; animals attempting to forage from the outside of a flower head go through all manner of futile contortions to obtain nectar and in a short time repo-sition themselves in the "proper" way. Pol-len is dispersed from a special region on the style known as the pollen presenter, and while foraging, animals both accumu-late large amounts of pollen on their snouts and make contact with the stig-matic surface. Even the most skeptical ob-server could hardly fail to be convinced that these animals effected pollination. The same result was obtained with *P. am-plexicaulis* and another Namaqua rock mouse.

Following these observations, we made detailed investigations in the field during the next three years. One perplexing tech-nical problem, which overshadowed all as-pects of the study, involved gathering data about an event that was difficult to ob-serve in nature because the flowering heads were cryptic and the pollinators nocturnal. We approached the problem in several ways. First, we demarcated several permanent study sites on Jonaskop in well-developed stands of *P. amplexicaulis* and *P. humiflora*; then, to obtain information

about the small mammals, we established a grid of one hundred live traps in dense stands of these plants. We were thus able to determine the species composition, density, activity periods, and movement patterns of the small-mammal community (at least those that were readily caught in live traps). The most prevalent small mammals associated with the two flowers under study were the Namaqua rock mouse, the Cape striped field mouse, and the spiny mouse. Animals caught in smaller numbers were elephant shrews, Verreaux's mouse, the dormouse, an African climbing mouse, and a small African species of house mouse.

Although these animals typically wet-groom their snouts after foraging, some pollen always remains to be transferred to the next flower. Because of its stickiness, the pollen cannot be dispersed by wind, and any grains found on animals' snouts can only be explained as the result of foraging for nectar in protea flowers. Virtually all of the approximately 150 small mammals we sampled had protea pollen on their snouts, although the quantities varied greatly. Since these animals presumably ingest pollen during wet-grooming, we reasoned that pollen should also accumulate in the feces—a prediction that proved correct.

To study foraging behavior, we observed and filmed captive individuals of three of the five types of small mammals mentioned above. Finally, to determine whether these animals preferred the protea species that we hypothesized were pollinated by terrestrial mammals, we conducted simple T-maze experiments. Conspicuous protea heads, which were typically pollinated by birds, were presented to the rodents along with samples of the cryptic species. In virtually every case, the animals foraged on the cryptic flower heads. In another experiment, we marked protea flower heads with powders that fluoresced under ultraviolet light; later the same night, we trapped animals bearing large quantities of the powder, usually on the snout and feet. With these strategies we obtained a considerable amount of pertinent information without ever seeing animals foraging on the flowers in nature (animals were both observed and captured on the plants, however, and many were trapped at the bases).

These observations do not mean that only small terrestrial rodents visit and pollinate protea plants with cryptic flower heads. A single species of pollinator, or even a group of related pollinating animals, is rarely solely responsible for pollen transfer in any plant species. Instead, there is typically a group of major pollinators for which the flowers are primarily adapted in terms of attraction and reward. There are usually secondary and tertiary pollinators as well, but these are not efficient pollinators.

Virtually all evidence supports the view that rodents are the primary pollinators of proteas; yet we know that many insects, especially bees and beetles, visit the flowering heads. For example, during the occasional warm days in early spring, African honeybees visit any protea flowering head in profusion. By enclosing newly opened flowering heads in wire cages that prevented visits from rodents but permitted relatively free access to bees and other insects, we were able to measure the pollination efficiency of the secondary and tertiary visitors. In one protea species, the exclusion of mammals reduced seed set by about 50 percent. In another, it was reduced approximately twentyfold, and a number of the caged heads set no seeds whatsoever. The individual florets of the flowering head are constructed so that insects can only effect pollination in the event that while collecting pollen from the pollen presenter they accidentally contact the stigma. Any insect that forages solely for nectar will not contact the stigma and pollination cannot occur.

L. Cooke; Animals Animals/OSF

ectar is held at the base of each floret in the protea flower
ad (cross section, below). While bees and beetles can gather
ctar without touching the pollen on the brownish red anthers,
ammals (such as the Namaqua rock mouse at left) cannot
sily avoid picking up and transferring the sticky pollen
ains, thereby fertilizing the plant.

L. Cooke; Earth Scenes/OSF

Both the shrubby vegetation of the ape and the area in which it grows are own locally as *fynbos* (literally, delicate rub). Despite being restricted to a nar- w coastal belt extending 50 to 75 miles rth and about 250 miles east of the ape, the *fynbos* has a distinctive enough mbination of climate, geography, and ant and animal species to be considered unique ecosystem. In its general aspect, e ecosystem is not unlike those of south- n California, central Chile, southeastern ustralia, and the lands surrounding the lediterranean itself. The *fynbos* has any characteristic features. For in- ance, there are almost no native trees or nuals, and many of the plants have ad- tations to survive periodic burning. But rhaps the most astonishing feature is e area's richness of flowering plant spe- es. Although it is restricted to the Table lountain sandstone, a soil notoriously de- cient in minerals, the *fynbos* supports a rodigious 8,850 species of flowering ants; 73 percent of these occur nowhere se on earth. The uplift and subsequent rosion of this sandstone formation have roduced many small mountain ranges ith diverse elevations, precipitation, and ils. The great diversity of species was no ubt influenced by this variety of habi- ts. The extent of the species richness is perhaps difficult to appreciate, but consider that the Cape peninsula averages about 5.7 miles in width and is approximately 20 miles long, yet it contains 2,250 species of flowering plants. By comparison, the entire Great Plains of the United States and southern Canada (about 800 by 1,200 miles) has only about 3,000 flowering plant species.

The *fynbos* on Jonaskop is largely undisturbed. The treeless slopes are densely covered with brownish green, thick-leaved shrubs representing an impressive array of species. Troops of the chacma baboon also live on Jonaskop and seem to play an unusual predatory role with respect to the rodent-pollinated proteas. They apparently tear the flowering heads from the bushes in order to suck the nectar; thousands of such heads often lie in piles of about five to fifteen in stands of *P. humiflora*. Other animals on Jonaskop include the klipspringer, reedbuck, and probably the leopard, but they are secretive and rarely seen. Local names of plants, such as *renosterbos* (rhinoceros bush), suggest the diversity of large mammals that inhabited the region prior to white settlement; today these animals are restricted to national parks.

Southern Africa has a rich bird fauna, and in extensive stands of bird-pollinated proteas of the Cape region, one can always see the protea bird. The protea bird's entire life history is inextricably linked to proteas. The bird obtains food (nectar) from the plant, usually nests in it, and also uses the brown, fluffy seed hairs to line its nest. The bird's breeding season also coincides with the flowering of certain proteas, and the young are partly fed on the nectar. On still nights one can occasionally hear eagle owls, one of perhaps a dozen raptors hunting in the African night skies. Night-flying raptors are a threat to the small mammals that pollinate the proteas, and it may be that the presence of such predators was an indirect influence on the evolution of cryptic protea species. Since a flower well hidden under foliage best protects its mammal pollinators, it also has the best chance of being pollinated and reproducing. These conditions, therefore, represent the geographical and biological settings in which rodent pollination evolved. What are some of its more interesting features?

One aspect of the system involves the pattern of adaptation between the flowers and the small mammals. These adaptations are all one way; the proteas have evolved to attract and reward small-mammal visits to the flowers without reciprocal adaptations by the small mammals for either enhancing foraging efficiency or effectively using nectar as a food. This lack of reciprocity contrasts sharply with most pollination systems, in which there are striking structural, behavioral, and physiological adaptations by both pollinator and flower. (Picture the hummingbird's long bill and a long, tubular flower.) Several observations bear on the questions of why such a system evolved, and why in the Cape region, but the answers must necessarily remain speculative.

Most of the mammal-pollinated protea species are found in small, restricted populations. Often they are associated with the specific soil types of relatively high elevations in the outlying Cape mountain ranges. In contrast, many bird-pollinated proteas grow in dense stands covering many acres; apparently, such a population structure is necessary to attract large numbers of the migrating flower birds associated with these proteas.

Many proteas, like this Leucosperma glabrum, *are pollinated not by nocturnal mammals but by birds during the day. Because they are exposed, upright, and colorful, the flower heads are easily seen by flying visitors.*

J.A.L. Cooke; Earth Scenes/OSF

The proteas adapted for pollination by nonflying mammals probably evolved from bird-pollinated prototypes and retain many of their features, such as large flowers, sturdy inflorescences, and copious quantities of nectar. The gradual development of small protea populations with highly specialized soil requirements probably resulted from the erosion that partitioned the Table Mountain sandstone.

This continuing restriction of population size may have ultimately provided earthbound mammals with several advantages over birds as pollinators. These small mammals are ubiquitous, nonhibernating, nonmigratory, and generalist feeders; thus they might be more readily attracted to an ephemeral and highly localized food resource than more specialized feeders such as birds. They might also offer more reliable pollination service than insects, such as honeybees and beetles, which are necessarily restricted in their activities by the long periods of low temperature and high precipitation typical of late winter and early spring in the Cape region, when these proteas flower.

Thus the high frequency of small, localized populations of proteas (and numerous other species in the *fynbos*, many of which face imminent extinction) may account for the independent evolution of pollination by nonflying mammals here and in southwestern Australia, where similar population structures occur. Whether this hypothesis can explain the apparent rarity of nonflying mammals as pollinators in the rest of the world remains to be tested.

The small, geographically restricted populations may also explain why there are no reciprocal adaptations by the pollinators. Typically, so few small mammals occur in a population of these proteas that any genetic recombination or mutation favoring better use of the resource would be swamped out by interbreeding with adjacent populations in areas without proteas. Furthermore, the resource is time limited—available only about four to six weeks of the year. For coevolution to occur among long-lived, continually active organisms, the resource must be available throughout the year. In the case of ephemeral insects such as solitary bees, coevolution can occur so long as the insects are active when the plants flower.

All pollination systems require two elements: an attraction and a reward (or promise thereof). The proteas' attraction is olfactory; they produce either a yeasty odor or a more pungent one reminiscent of rancid butter. Each basic odor has slight variations, depending on the species. The reward is nectar.

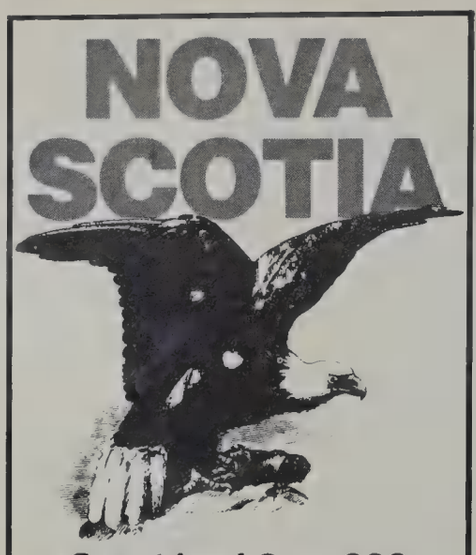
The nectar has several distinctive features: It is secreted in relatively large quantities (by the milliliter) and has a high sugar content (roughly 40 percent), of which about 50 percent is sucrose (table sugar), giving the nectar a particularly sweet taste. The relatively large quantities of nectar produced effectively attract small mammals, which require proportionately greater energetic rewards. Initial estimates, however, suggest that the total nectar production of a protea population can supply the energy requirements of the small mammals on our study sites for only about eight days of the year. Thus the nectar cannot be an important part of the animals' diet. Other populations of the same species of small mammals, living only a short distance from the proteas, are primarily seed eaters that never have access to nectar, yet they survive without difficulty. Why then should the small mammals bother to visit the flowers and forage for nectar at all?

The answer may rest with the remarkably sweet and tasty nectar. Rodents, and many other mammals, have a "sweet tooth." Consider for a moment the millions of acres of agricultural land devoted to sucrose production for human consumption, not to mention the worldwide honey industry. These products are not only unnecessary to the human diet but are often deleterious. Yet sugar craving provides the basis for the entire "junk food" industry, from soft drinks and breakfast cereals to confections. Proteas appear to have employed the junk food principle to attract small mammals to their flowers. In other words, the sweetness of protea nectar is so enticing to small mammals that the flowers do not have to supply much of it in terms of the animals' overall energetic needs.

Though it is still too early to know just how common pollination by nonflying mammals is, the phenomenon is obviously rare compared with pollination by such animals as bees, moths, and bats. We do not know why so few land animals became pollinators. It may simply be that flying animals—such as bats, bees, and moths move pollen more efficiently. Throughout evolutionary history, plants have acquired traits that attract and reward the more efficient pollinators. Robert Sussman and Peter Raven have argued that pollination by nonflying mammals was more common before the evolution of the flying mammals (bats), which outcompeted the less mobile terrestrial and climbing species, particularly in the tropics. They suggest that this is why most pollination systems that depend on nonflying mammals for pollen transfer are today restricted primarily to regions where flower-feeding bats are absent.

What might be the consequences if large numbers of plants depended on pollination by nonflying mammals? First, the nature of the reward should change from the junk food variety to a nutritionally valuable resource, since animals would have to use it as a major dietary component. Consequently, the plant–animal interaction should then shift toward a coevolved system, as in the case of proteas and protea birds. This is probably the situation in parts of Australia where several mouselike marsupials, such as the honey opossum, have become adapted for diets of nectar and pollen. Yet even here, species adapted for pollination by nonflying mammals probably do not form a major component of the plant community.

For the past several decades, pollination systems have been extensively studied to elucidate a broad spectrum of ecological and evolutionary questions, such as mutualistic and coevolutionary phenomena, optimal foraging, gene flow, and energetic relationships. Thus, in addition to its intrinsic interest, the discovery of a wholly new system of pollination provides a new model for experimental analyses and also tests whether current theory for the origin and function of pollination systems is adequate. □



Count 'em! Over 200 bird species live here.

You can see bald eagles nesting around the Bras d'Or lakes in Cape Breton. (Maybe relatives to the young birds given to the US Wildlife Service for their re-stocking programs.)

Osprey soar and swoop above McNabs Island and along the South Shore. Cormorants stand guard at Pictou, and you'll find a fascinating collection of shore birds patrolling Evangeline Beach.

However, the mecca for bird watchers is Briar Island off Digby Neck. Here, particularly in late summer and fall, the whole area is alive with birds of every description, resting and feeding before continuing their incredible journeys.

Come and take a look for yourself. Your U.S. dollars are worth 25%-30% more up here. World-class ferries sail between Portland and Bar Harbor, Maine and Yarmouth in Nova Scotia.

A Library of Bones

If all the bones in the American Museum of Natural History were dumped in Central Park, they would form a pile well over three stories high and 200 feet in circumference. A very rough calculation indicates the pile would weigh about 1,000 tons and contain about 50 million bones, representing the remains of more than 750,000 animals.

The Museum's bones come from every corner of the globe—from Outer Mongolia to East 59th Street. The people who found them endured blizzards, sandstorms, fights with bandits, and a host of hardships to get them. Some collectors even risked their lives or spent their personal fortunes in the effort. Almost all the bones—more than 99 percent—were collected for scientific purposes and are not on public display. More than two hundred scientists and their assistants conduct research in the Museum, and much of it focuses on bones.

One such scientist is curator Malcolm McKenna, a paleontologist who specializes in fossils of early mammals. There is no mistaking the subject of his research—boxes of fossil bones, all carefully labeled and numbered, cover most of the tables in his spacious office. McKenna explains that much of his work deals with bones he himself has gathered in the field. During his thirty or so years in paleontology, he has prospected on just about every continent, looking for extremely rare fossils of early mammals in regions as distant as Patagonia and Greenland.

McKenna brought out a plastic box filled with his recent finds, which looked like tiny chips of stone but turned out to be hundreds of minuscule fossil teeth, tiny jaws a quarter-inch in length, together with other irregular bits and pieces of fossil bone. In all, the box held less than two ounces of fossils. They dated, McKenna said, from about sixty-six million years ago and were discovered in Cretaceous beds at Lance Creek, Wyoming.

The fossils are rare. "To get this little box of jaws and teeth," he said, "a field crew of eight people had to process five tons of matrix [fossil-bearing rock] every day for a week." McKenna spends most of his summers in the field collecting fossils such as these. Over the years, he has developed a collecting method that differs radically from earlier methods. He collects entire fossil communities—fossil ecologies—rather than individual specimens; to do this, McKenna has to extract almost every fossil larger than a small pebble from a particular deposit.

"I want to get the best representation of life for that particular moment of time," he explained. "My research requires the highest-resolution data—the most detailed and complete picture possible." To accomplish this, McKenna and his field crew dig up the matrix, which at Lance Creek is made up of ancient channel sands crossbedded with layers of clay. (The highest concentrations of the fossils McKenna is after can be found in these "fossil garbage dumps" in ancient stream beds, where flash floods and other processes have deposited a great assortment of bones, many of them contained in carnivore scat.) First, the matrix is put in water, then it is sifted through a fine wire-mesh screen. The screen catches thousands of pebbles—and, if McKenna and his crew are lucky, a fossil tooth or two. In one day, working in assembly-line fashion, the crew can process 550 boxes of matrix, each weighing twenty pounds, for a total of about five tons. "It's very tedious work," McKenna said. "You have to go through a lot of beer and Cutty Sark just to find one

ssil." (Indeed, one of McKenna's col-
agues named a new species *Cuttysarkus*
cnallyi because the discoverer had been
omised a bottle of the scotch if he found
mammal jaw with six or more teeth in
)

McKenna's collecting method is effi-
ent. "The first day we spent at Lance
reek in 1956," McKenna said, "we col-
cted more fossils than everyone else
ce the fossil locality was discovered."
t the fossils are so rare that an entire
mmer's work could fit in a small piece of
rry-on luggage for the return flight to
ew York.

McKenna poked his finger around the
x of fossils. "This box represents," he
id, "a picture of the animal life of that
rticular area at a particular moment in
ne—in this case, about sixty-six million
ars ago, around the time of the mass ex-
ction at the end of the Cretaceous."
ance Creek has fossils of about eighty
nds of animals, including fishes, lizards,
y and large dinosaurs, frogs, salaman-
rs, birds, and early mammals. "I keep
e mammal bones," he said, "and spin off
e rest of the fossils to other scientists."

"What can these bones tell us? An ex-
aordinary amount, it turns out. There
e many levels of 'boniness.' Bones have
exterior shape, which tells us about the
atomy of the animal and what it did for
living. Bones have an interior structure,
hich can provide clues about whether
e animal was warmblooded. Some bones
ve growth rings, which indicate whether
e animal lived in a variable climate and
d to slow down for a period every year.
ones also have a microscopic structure,
hich can show such things as the metab-
ism of the animal."

Since teeth survive better than other
ones, they make up most of the contents of McKenna's box. Mammal teeth are almost a fingerprint of the animal—they are highly complicated structures with ridges, valleys, spikes, ribs, ripples, pits, and points. Few species have teeth that look exactly the same as those of another species. Consequently, a paleontologist can sometimes identify an animal fairly closely by looking at a single tooth and can usually identify it with certainty from a jaw with two or three teeth. Equally helpful, mammalian teeth don't get any bigger as the animal grows in size. Teeth remain constant for a given species, except for wear.

Once McKenna has identified the animals living in a specific community, he moves on to some of the larger questions. Bones can reveal something about the behavior of the animal, for example. "Take foot bones," he said. "What was the animal doing with its feet? Was it hopping, swimming, galloping, climbing in trees?" Since bones have marks where ligaments and muscles were attached, the paleontologist can actually determine an extinct animal's musculature and reconstruct the form of the animal itself.

Once paleontologists know what the animal looked like, they can start reconstructing its habitat. If the animal was a hopper, for example, it may have lived in an arid, sandy area. If the animal climbed trees, its habitat is self-evident, even if no tree fossils are present.

McKenna continued. "Much of this information can be found by studying this little box of fossils. You can actually work out the census structure of the community with these fossils. You can tell a lot about its ecology. How did the animals interact? For example"—he paused to pick out a tooth from the box—"this mammal tooth passed through the alimentary tract of a

Audubon's *Birds of America* Complete!

Catalog of the most recent sale of Audubon's peerless BIRDS OF AMERICA, owned by the Earl of Caledon. (Auctioned at Sotheby's, January 1985.) Features illustrations of every print (all 435), including 38 in full color! List of latest auction prices for each print included. An excellent reference for Audubon collectors and anyone interested in this great naturalist.

TO ORDER

A limited number of the Sotheby's BIRDS OF AMERICA catalog have been reserved especially for Museum Members at the special price of $14 each, plus $2 shipping. Please send check to Members' Book Program, American Museum of Natural History, Central Park West at 79th Street, New York, NY 10024. To order by phone (VISA or MasterCard accepted) call toll free 800-247-5470.

big reptilian meat eater, such as a crocodile. How do I know? The tooth has been etched by stomach acid—see, it looks frosted. I suspect it was a crocodile because crocodiles have very acidic stomachs. So we know what animals were eating what."

But this is just the beginning, according to McKenna. "If you want to answer the largest questions in science—and this is the goal of most scientists—you have to study the highest-resolution data possible. You can spin theories with a bone here and a bone there, but what you really need are many, many bones of many kinds from one locality at one time.

"By looking at fossil assemblages in a number of areas, you can correlate assemblages to within about one percent of their real age. Then, by studying successive layers, a paleontologist can learn how the community and the climate evolved over time. If a group of species suddenly went extinct, the paleontologist can look for the reason. Thus, even a small area can yield information about the earth as a whole."

This can be taken even further. By comparing two sets of layers in different sites, paleontologists can gain data that will help draw a hypothetical map of the earth as it appeared at a point in the distant past. "Let's say you're studying two localities, one in France and one in Wyoming," says McKenna. "In layers about fifty million years old in France and Wyoming, most of the animals are normally quite different. But about sixty million years ago, European and North American deposits began to have many animals in common. What do you conclude? Possibly that some sort of connection—a land bridge—was present between Europe and North America for a while. By looking at other scientific data, you recall that huge lava flows occurred where Greenland was close to Scotland. Europe and North America were much closer together at that time. Thus, you hypothesize that a land bridge developed between sixty million and fifty-five million years ago across the North Atlantic. Five million years later the two faunas—in Wyoming and France—were different again. Therefore, you conclude that the sea encroached upon the land bridge and cut off that particular route of interchange, after which the faunas of the separated areas evolved independently."

The amount of information bones can provide is limited only by the questions we ask. One question McKenna has been working on is whether the dinosaurs died out suddenly or gradually, and he collected the Lance Creek fossils because he knew the strata dated from the end of the Cretaceous, when the dinosaurs becam extinct.

"When did the dinosaurs disappear' McKenna asked. "Was the extinctio caused by a bolide impact? Paleontol gists find that the dinosaurs became e tinct *before* the event that left a layer iridium and other apparently extraterre trial debris around the world. There is small but significant thickness of roc without dinosaur fossils underneath th iridium layer. That they could have bee around but not found is possible, but th chance of that is about 3 percent or eve less. Now this is a fascinating observatio Could the various extinctions *and* th bolide impact have been caused by th same thing? Here's where paleontolog and other scientific disciplines can pr vide important information. If we con bine our data with astronomical data, w can tell something about the history of th earth in relation to the solar system.

"Paleontologists have noted a periodi ity in mass extinctions. Astronomers hav noted a periodicity in the path of the sola system as it passes back and forth throug the galactic plane. Geologists have noted periodicity in the formation of ancient me teorite craters on the earth. Geophysicist have suggested a periodicity in magneti reversals. Could all these things be re

China is a must in your travels. And it's a must to travel there like Royalty on Royal Viking Line. No one else shows you every important place—at just the right unhurried pace. With every comfort and convenience. A spaciousness approximating grandeur!

Our 13-day fall cruises between Hong Kong and Japan depart this September and October. With a free three-day land package in Hong Kong, two complimentary nights at one of Beijing's modern, new hotels, and all shore excursions included.

If the readers of *Travel/Holiday* voted us #1 in the world, you know we must be #1 to China. We're certainly the most experienced. Come see for yourself!

ıted?" McKenna noted that a number of ıeories relate some of these observations.)ne theory, for example, hypothesizes the xistence of a dark companion star to the un that periodically swings close to our olar system and sends comets plunging ıto earth-crossing orbits, some to strike he earth.

"The point here is that all the various cientific disciplines come together and êst each other's theories. What we are do-ng—in the Museum and elsewhere—is outting together a general picture of the arth. We want to construct the entire his-ory of our planet, not just the history of ınimal life. This is real natural history—ıot just biology. We're not the American Museum of Biology. What we are working on here in the Museum has consequences ınd implications throughout science, from ıstronomy to geophysics.

"The reason we collect bones is to build ıp a library of *facts*. It's not postage stamp collecting by any means. Bones, and in-deed all scientific collections, differ from books in that books are opinion and inter-pretation while specimens are facts. Mu-seums are different from universities. Bones are one of our greatest links with he past—they are our record of extinct vertebrate life on this planet."

Douglas J. Preston

At the American Museum

Adirondack Anniversary

On May 15, 1885, the Adirondacks in upstate New York became a forest preserve. The Membership Office will mark the *Adirondack Centennial* with a special exhibit and program on Tuesday, May 14, in the Hall of Northwest Coast Indians and the Auditorium. Between 6:30 and 7:30 P.M., Museum scientists and visiting specialists on the Adirondacks will set up special displays on the region's wildlife, geology, and ecology. At 7:30 P.M., in the Auditorium, Peter Berle, former commissioner of the Department of Environmental Conservation, will narrate a slide show of striking photographs of the Adirondacks. The program is free for members, $3 for nonmembers. Tickets are required; for information call (212) 873-1327.

Margaret Mead and Film

Margaret Mead strongly advocated the use of film in anthropological fieldwork. Paul Byers, who studied with Mead, will show several of Mead's classic films, as well as examples of footage she used in her teaching, and discuss her use of the medium. *Margaret Mead and Film* will take place on Wednesday, May 15, at 7:00 P.M. in the Auditorium and is free to the public.

Celestial Rhythms

The Planetarium will present an electronic concert of contemporary and classical music by three Planetarium musician-composers. Accompanied by an array of laser and special effects, the musicians will play selections from *Star Wars, The Right Stuff,* and Pachelbel's *Canon in D Major,* among other works. For ticket information call (212) 873-5714.

Matteo

Matteo and his EthnoAmerican Dance Theater will offer a program of dance from around the world on Tuesday, May 21, at 7:30 P.M. in the Auditorium. *Dance: Sounds, Symbols, and Styles* will feature dances from the Middle East, India, southern Spain, and other regions. Tickets are $3 for members, $6 for nonmembers; for more information contact the Membership Office at (212) 873-1327.

Bright and Dim Planets

by Thomas D. Nicholson

Venus takes a prominent place in the morning sky this month, having brightened swiftly since inferior conjunction (passing between the earth and the sun) in early April. Although it moves farther west of the sun this month, it remains relatively low in the dawn sky. This is a good opportunity to look for the planet in daylight, however. At about 11 A.M. to noon, it will be roughly 45 degrees west (right) of the sun and at about the same elevation. Venus is bright enough to see without binoculars, but they will help in finding it.

At dawn, while Venus is in the east, Saturn and Jupiter are in the west—Saturn dim and just about setting, Jupiter very bright in the southwest. Saturn moves into the evening sky this month, rising in the southeast at about sundown. Jupiter remains a morning star until early August, rising about four hours ahead of the sun. Mercury is also a morning star, but Mars is an evening star. Both are dim and poorly placed for viewing.

Events in the calendar are given in local time unless indicated otherwise. (Add one hour for daylight saving time.)

May 1: Mercury is at its greatest distance to the sun's right (westerly elongation), but in May that means more southerly as well. Despite the distance, this is not a good elongation. The moon starts out the month in great shape—bright, fat, and gibbous in phase, up until about 4:00 A.M. It is midway between Virgo's brightest star, Spica (left of the moon), and Leo's Regulus (right of the moon).

May 2–3: The moon's position on these nights brackets Spica, moving from right to left of the star on the 3d.

May 4: There is a total lunar eclipse today, but because it occurs over parts of

Celestial Events

sia, Europe, and Africa—before the oon rises in the Americas—we will miss We will, however, get the perigee spring des. Full moon is at 2:53 P.M., EST, and erigee is about fifteen hours earlier. High des will be affected tonight and on the orning of the 5th.

May 5: Test the brightness of tonight's bbous moon by looking for Saturn and ntares (Scorpius's bright star). The oon splits them as they rise in the east af- r dusk—Saturn above the moon, An- res just below.

May 6: The moon rises after and below ntares tonight and is in the "thirteenth onstellation of the zodiac," Ophiuchus, hich occupies a small region between corpius and Sagittarius.

May 9: Venus entered the morning sky nly five weeks ago, yet here it is at great- st brilliancy as a morning star. It rises arly but remains low in the dawn sky, al- hough its brightness will make it visible if he eastern sky is clear.

May 10: The moon is in the morning ky, near Jupiter in Capricornus.

May 11: Last-quarter moon, at 12:34 M., EST, is entering Aquarius. Mars, ill trailing the sun in the evening, drifts owly east, past Antares, in Taurus.

May 15: When it reaches the point in he sky opposite the sun, Saturn becomes n evening star, rising with sunset and set- ng at sunrise. It is still up at dawn, in the est. The bright object near the moon at awn is Venus.

May 16: This is probably the last morn- ng to see the late crescent moon before it noves between the earth and the sun. Apogee moon (farthest from the earth) oc- urs later in the day.

May 19: New moon, in Taurus, is at :41 P.M., EST. A partial eclipse of the

American Airlines presents . . .

AAloha condo

All-Suite HAWAII

hcp Hotel Corporation of the Pacific

Enjoy the best of both worlds . . . the value of a condo and the services of a hotel . . . with the AAloha Condo tour package.

Fly American Airlines in wide body comfort to your own Hawaiian condominium. Altogether you can choose from 14 resorts where every room is a studio, 1, 2 or even 3-bedroom suite. All are managed by Hawaii's leader, Hotel Corporation of the Pacific.

And, all offer the services of a fine resort . . . like daily maid service, swimming pools, jet spas and complimentary parties. Most have restaurants and tennis is always free. Plus, you get the convenience and value of a complete kitchen.

Prices begin at only $16 per person* for four including an Avis rental car with ***unlimited free*** mileage. Best of all, you qualify for these low rates even when you fly on American Airlines' lowest fares.

* Land rates only, based on 4 persons, 2 night minimum stay.

See your travel agent or call American Airlines toll free

HAWAIIAN AIR

sun, visible from parts of Asia, Alaska, Canada, and Greenland, occurs today.

May 21: Mars is just below the early two-day-old crescent moon this evening. They are both in Taurus, to the left of Aldebaran.

May 22–23: The widening crescent moon is passing through Gemini. The stars above the moon on the 23d are Pollux and Castor.

May 26: Regulus, in Leo, is just below the waxing crescent moon, which is almost at first-quarter.

May 27: First-quarter moon is at 7:56 A.M., EST. Tonight it is in Leo, with Regulus and the curved Lion's head to its right, and Denebola (at Leo's tail) above and to its left.

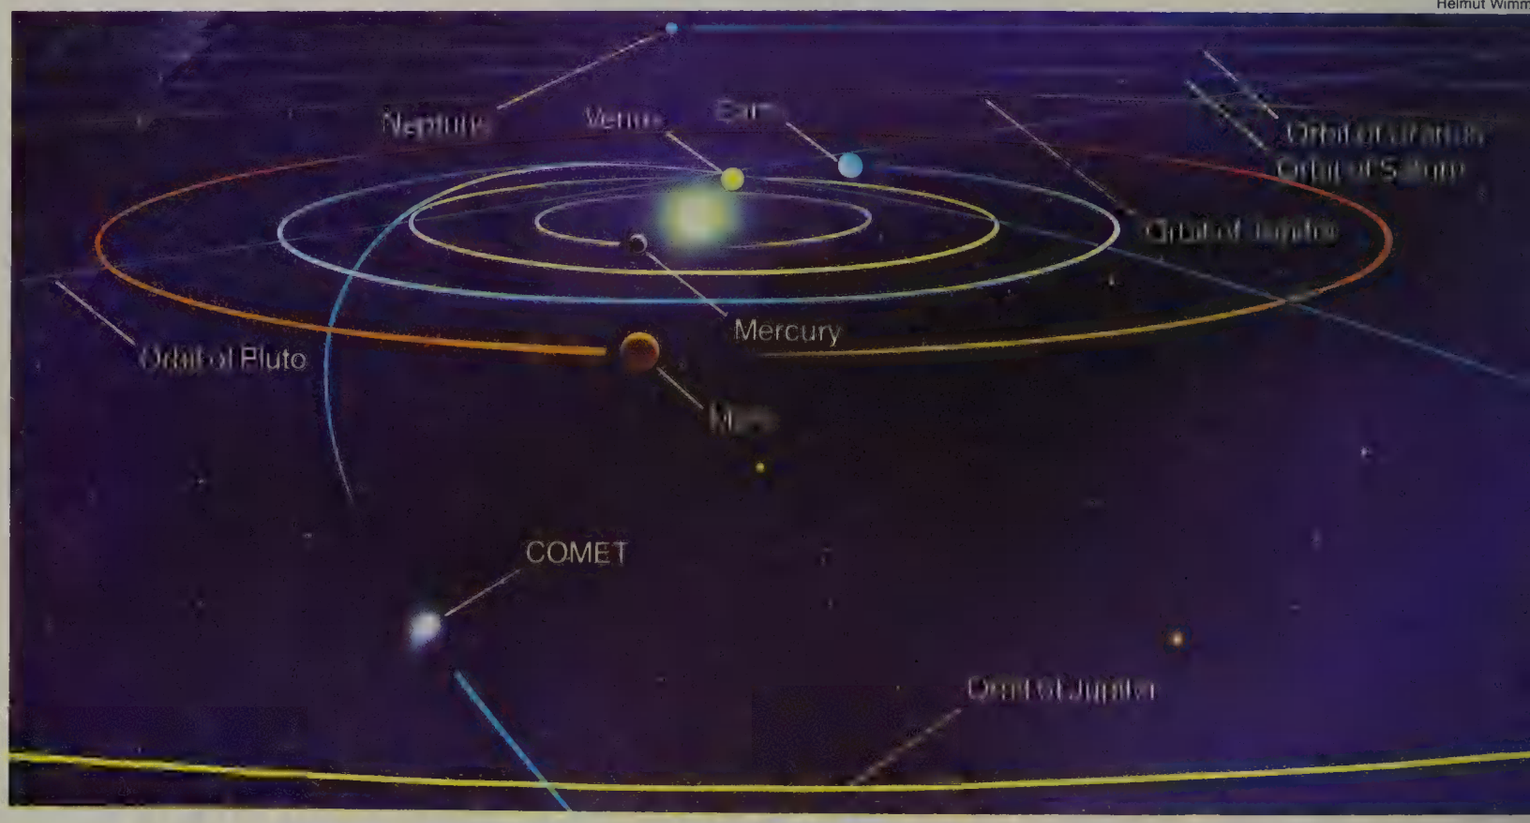
May 30: The star below the moon is Spica, in Virgo. This is the second time in May the moon has passed Spica. Note that the last time it passed the star (twenty-seven and one-half days ago, the 3d), the lunar phase was much late

May 31: The moon, waxing through i gibbous stage and three days short of b coming full, ends the month in Libra, mi way between Spica (to its right), and A tares (to its left).

Editor's Note: The Sky Map in the Apr issue shows the constellations and stars f this month and gives the times for use.

Halley's Comeback

Helmut Wimm



Halley's comet is still in the evening sky in May, above the western horizon at sundown but setting an hour and a half later. A small, dim, starlike object near the Hyades (the "face" of the Bull), Halley is still many months away from looking like a prominent comet.

Popularly, comets "race aross the sky," but actually, they are among the "tortoises" of the solar system. This month's illustration shows Halley's comet between the orbits of Jupiter and Mars (though well south of their orbital planes). But if you compare the May illustration with April's, you will see how little the comet has advanced in its goal of circling the sun. Despite its orbital speed (now some 41,000 miles per hour with respect to the sun) and its motion since mid-April (about 369 million miles, bringing it some 29 million miles closer to the sun), the comet has advanced only one-tenth of the way between the orbits of Jupiter and Mars.

Halley's comet is racing faster and faster toward the sun. On the first day of the year, its orbital velocity was about 35,000 miles per hour; by the end of November, it will almost double that, closing its distance to the sun at a proportionally accelerating rate. The comet is already 122 million miles closer to the sun than it was at the beginning of the year. Not so with its distance from the earth, however. At mid-May, Halley's comet is more than 50 million miles farther away from the earth than it was on January 1. The reason is the earth's orbital motion, which takes us alternately closer and farther from the comet's orbit.

Since the beginning of the year, Halley's comet has been an evening star. The earth was closest to it—about 400 millio miles away—on January 13, when it passed between the come and the sun. The earth moves gradually away from the come until May 2, when the distance between them is 455 millio miles. During May, the earth and Halley's comet move closer by the end of the month, they are about 444 million miles apar (and closing). Shortly thereafter, on June 12, the earth's motio takes the comet from the sun's left to its right, into the morning sky, where it will be until late November.

When will we see Halley's comet? Perhaps not until Novem ber. This month, however, we can see a meteor shower associ ated with Halley's comet—the Eta Aquarid—if the weather co operates. The shower is at maximum early on the morning o May 4. If you get up at about 1:00 A.M. and watch patiently, you may see a meteor streaking across the sky. Unfortunately, the moon will be up in the southwest, nearly full. But the Eta Aquarids are known as swift, often bright objects, and the brightest ones may be seen easily through the scattered moon light. If you do see one (perhaps even on the morning of the 3d or 5th, when there may still be twenty meteors per hour), you may be looking at a piece of Halley's comet, blown off the comet long ago and following the same orbit around the sun. It will finally enter the earth's atmosphere to become a meteor. Don't worry if you miss the meteors this year. There will be more next year, and every year in May, if this faithful shower holds up. (Still another meteor shower is linked with Halley's comet—the Orionid—seen each year in late October.)

INTRODUCING
MEMBERS' NEW YORK WEEKEND

A special New York tour program designed exclusively for our Members. It's a convenient and economical way to enjoy all the wonders that New York and the American Museum of Natural History have to offer.

THE TOUR PROGRAM INCLUDES:

Two nights in one of New York's finest hotels. Stay at the Waldorf-Astoria, The Plaza or Parker Meridian. Minutes away from New York's famed theater, shopping and eating districts and only a short ride away from the Museum itself.

Two complimentary meals: Enjoy a full breakfast at your hotel and a spectacular brunch at the new American Museum Restaurant, a charming greenhouse-like dining room nestled in one of the Museum's interior courtyards.

The Official Museum Guide and a Highlights Tour: As soon as you make your reservations we will send you the Museum's Official Guide book to introduce you to our fabulous treasures. And then when you come to the Museum, take a Highlights Tour which provides fascinating insights into the Museum's most popular halls. You'll see the Star of India sapphire, Tyrannosaurus Rex, the enormous Blue Whale, a ceremonial canoe of the Haida Indians and much more. After the tour relax in our private Members' Lounge or take advantage of your Members' discount at one of our gift shops.

Free Planetarium and NatureMax Tickets: Journey through the heavens in the Planetarium's famed sky theater and enjoy the cinematic experience of a lifetime at NatureMax, with a movie screen four stories high and over sixty feet wide. (One of only 20 such facilities in the Western Hemisphere!)

Personalized Service: Our travel service representatives at Planetarium Travels Inc. will help you customize your New York Weekend to suit your needs and tastes. They will be glad to arrange for theater or concert tickets, reservations at New York's top restaurants, a carriage ride through Central Park or a special city tour. They can also arrange for special discount air fares to New York on American Airlines, the official airline of the Members' New York Weekend.

Special Exhibitions: The Museum presents an exciting schedule of special exhibitions throughout the year. For example, opening this April: *Maya: Treasures of an Ancient Civilization,* the first comprehensive exhibition of the art treasures of the Maya, and *John James Audubon: Science into Art,* commemorating the 200th anniversary of his birth.

TOUR PROGRAM PRICE: $92.50 per person, per night, tax included (based on two nights double occupancy, includes accommodations at deluxe hotel, two meals, Planetarium and NatureMax Tickets, Museum Highlights Tour and the Museum's Official Guide book). Rates also available for families and individuals.

Call or write today for reservations, brochures and more information.

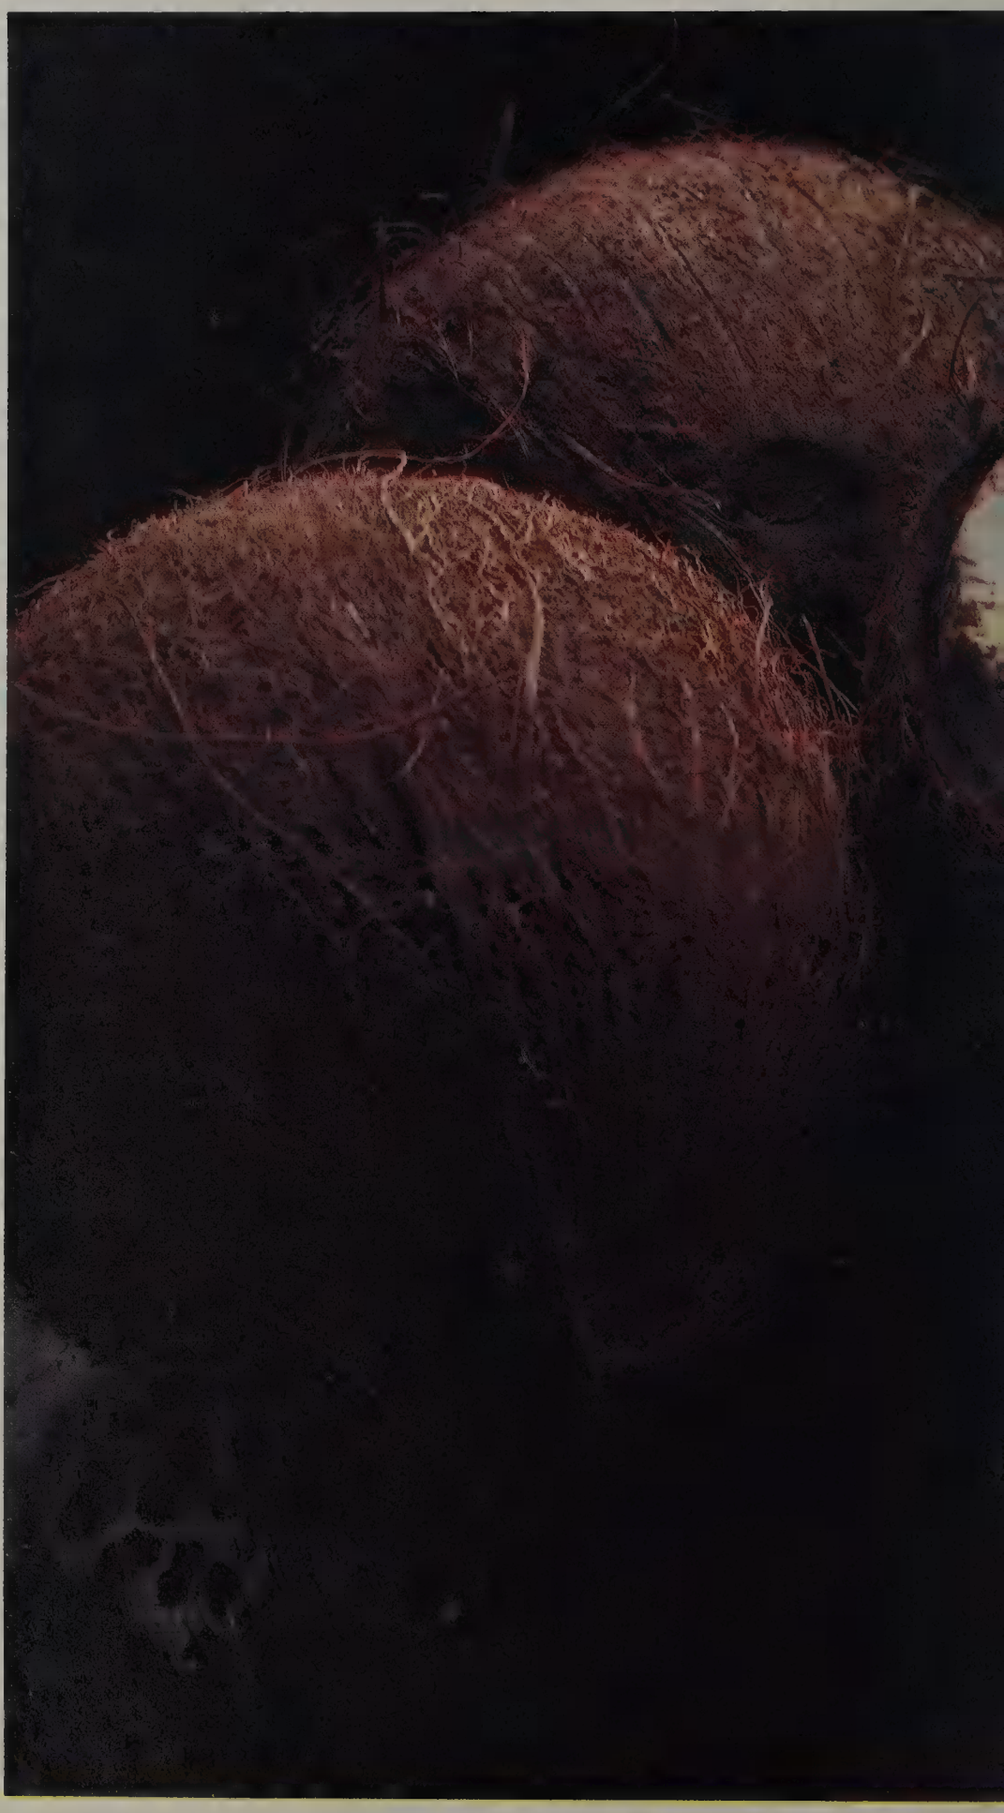
Camera-ready art is required for display ads. A tearsheet or copy of the page with your ad will be sent upon publication.

The Perilous Seed

Coconuts may be hazardous to your health

by Raymond Sokolov



The coconut is a very large seed that can kill. When I say this, I am not primarily thinking of people who have died accidentally when hit by a falling coconut. Nor do I have in mind the fatal accidents that inevitably result when harvesters going up into tall coconut palms fall to earth. Certainly, I was startled to read in 1982 that Major Julio de la Gente of the Philippine army had managed to detonate a bomb made entirely from residues of coconut oil. According to the official Philippine news agency, the 6.6-pound bomb, buried four feet under gravel near Zamboanga, blew debris as far as 656 feet and was described by Major de la Gente as "stronger than ordinary dynamite."

Such a device could obviously kill, but I have not subsequently heard reports of coco bombs exploding in U.S. embassies or otherwise supplanting dynamite or plastic. So I have tended to dismiss the de la Gente discovery as yet another Philippine gesture toward maximizing the use of a major local crop. This is an understandable preoccupation in a country so dependent on coconuts. Not long ago, plummeting coconut prices sent officials into a tailspin that had the prime minister, Cesar Virata, launching a campaign against imported U.S. junk foods and urging—on nutritional grounds—greater consumption of coconut oil and milk.

It is precisely on those grounds that all objective observers agree that the coconut is a dangerous seed. This is a difficult notion even for non-Filipinos to accept. From time almost immemorial, *Cocos nucifera* has charmed and delighted people with its stately fronds swaying high above tropical beaches. Writers of ancient Sanskrit called it *kalpa vriksha,* "the tree that provides all the necessities of life."

And with reason. The shells, the leaves, the wood, the fiber from the husk—all are useful, multifariously so. And it is no wonder that *C. nucifera* has been more widely planted than any other agricultural tree. But the age-old human enthusiasm for the coconut began and spread in what might be called palmier days, before we knew or had reason to care about cholesterol.

I hardly need to remind readers of *Natural History* that cholesterol and the satu-

WONDER TILLER

At Just 20 lbs, What It Will Do Will Amaze You!

If your garden is less than an acre, you need a big, expensive tiller like you need rabbits. What you need is *one* small, precision machine that can do a *variety* of jobs in the garden and around the yard... quickly, easily, neatly and economically.

The exciting Mantis Tiller/Cultivator is changing the way Americans garden. It weighs just 20 pounds so *anyone* can use it. It starts with a flick of the wrist... cuts through tough soils... turns on a dime... weeds in and around plants, between narrow rows and along fence lines... and runs *all day* on a gallon of gas! What's more, with its inexpensive attachments, it quickly becomes a *furrower, lawn aerator* or *de-thatcher,* a power *edger,* or a *hedge trimmer!*

3-Week In-Your-Garden Trial

Best of all, you can try the Mantis — risk-free! If you don't *love* it, simply return it for a full refund.

Mantis' tines are warranted *for life* against *ever* breaking and its engine has a *lifetime* Replacement Agreement!

Why spend another season without the little tiller that's changing the way Americans garden?

Cracking coconuts on the Gilbert Islands

rated fats associated with its presence in the cardiovascular system are openly condemned by almost everybody licensed to preach about diet and health. And since the oil that lurks in abundance in the white flesh of the coconut's kernel is lethally saturated, the coconut is currently anathema to right-thinking folk. Why even food writer Craig Claiborne, after expatiating last summer in the *New York Times* about a favorite Brazilian chicken recipe (*xin xin de galinha*) aslosh in the offending arboreal milk, felt obliged to warn his readers that it should be "reserved for special feasting. . . ."

I doubt that very many Americans run a serious risk of death because of daily meal plans chockablock with *xin xin de galinha* and other tropical dishes based on coconut milk. Those of you who have tasted these foods in Brazilian and Southeast Asian restaurants will understand the unctuous appeal of coconut milk. But a mass conversion of Manhattanites to the dangerous diet of Bahia or Zamboanga is a highly improbable catastrophe. Coconut oil is already found everywhere; it is an occult presence in the most mundane foods. The food industry adds it to numberless products, some of them labeled, others exempt from such revelation. Until recently, coconut oil was the leading edible oil (best known perhaps as a major constituent of margarine), but the more healthful soybean oil overtook it.

During the brief period of my misspent youth that I passed in the food news department of the *Times,* I was amused to receive periodic bulletins from a trade organization representing Philippine coconut desiccators. How exotic, how far from my daily concerns, I thought. But it is precisely those Filipino businessmen who dr and shred the coconut flesh (called copra to press out the coconut oil. And that o still competes with more expensive bu less saturated fats and oils for a place i many processed foods sold to unknowin Americans otherwise obsessed with the re silience of their aortas.

What is to be done?

I propose a two-pronged plan. First read labels on food packages closely an avoid products that list coconut oil (and it saturated cousin, palm oil) among the firs few ingredients. This is a tacit signal tha coconut oil is a major component of th food. Since you wouldn't have tasted th coconut in these industrial foods anyway you have lost nothing, except possibly a few pennies, and if you also keep you consumption of saturated fats—particu larly animal fats—low, you will have con tributed significantly to a sensible dietary program.

Now that you are a paragon of nutri tional caution, you can follow the second half of the plan with relative impunity. A Mr. Claiborne suggests, on festive occa sions you can afford to indulge in the gas tronomic delights of coco cuisine, thereby joining millions of people in other places who have developed hundreds of rich, fra grant, and perilous dishes that no one should miss—in moderation.

The coconut itself is the main obstacle to such enjoyment. Fortunately, you and don't have to remove the fibrous and bulky husk ourselves. Every supermarket carries husked coconuts. The spherical

wn, hairy shell is still there, but it is rel-ely easy to remove.

Having selected a coconut by the aural-ical method (make sure the shell isn't cked and that you can hear water slosh-around inside, indicating freshness), e it home and crack it.

f you like to drink the water, pierce a ıple of the coconut's eyes with an ice-k or a corkscrew and pour it through a ainer. (It is to these eyes—there are ee—that the coconut owes its name. anish explorers thought they looked e the eyes and nose of a monkey; Span-slang for monkey face was *coco.*) Oth-vise just crack the shell with a hammer. e water will drain away and the kernel l split into several large pieces. Nor-lly, it is no problem to pop the meat m the shell with a screwdriver. But if u heat the coconut in the oven before acking it (or afterward), the meat sepa-es from the shell even more easily.

Now you have the meat, but the meat s a coarse brown skin on it. If you were ending to serve the actual flesh, you uld have to cut away the skin with a getable peeler or a knife. This is unnec-sary and a waste of time if you are just tracting coconut milk. The skin does not lor or otherwise contaminate the milk. just cut the meat into pieces and rate" it in a food processor or blender. In the old days, you would have had to l away with a hand grater, but the metal ade of a processor is now the tool of oice. Soak the meat in three cups of iling water for a half hour and then pro-ss. Squeeze everything in the processor in a double layer of cheesecloth. That ll extract as much milk as is worth your hile. In the Third World they go back for econd extraction, and then a third, with pidly diminishing returns.

The white residue left after extraction is lled copra cake or poonac. You won't e it, but your dog might, in small nounts. Poonac is often used for animal dder in coconut-producing countries.

This extraction process is not as labori-s as it sounds. But you can avoid it alto-ther if you can find canned coconut ilk. In *The Classic Cuisine of Vietnam,* ach Ngo and Gloria Zimmerman recom-end a concentrated milk sold by Stan-od. Mrs. Ngo, a coconut connoisseur nose mother's garden in Vietnam had ur varieties of coconut growing in it—e for water, another for soft edible flesh, d so on—thinks canned milk is superior milk extracted from the less than ide-ly fresh kernels sold in this country.

Prepared coconut cream is also avail-le here, usually as an ingredient for ña coladas, but it will not work in recipes

SCANDINAVIA
On the Five-Star Polaris

Experience Scandinavia this summer from the luxury of the Polaris. Choose from June through August departures that feature the fjords; or the grand capitals of the Baltic; others that include Leningrad and Moscow. We offer New Arctic Adventures to Spitzbergen and the North Cape, to the lands of the Midnight Sun.

Your guides are well known authorities on Scandinavia. Your ship is the yacht-like Polaris, accommodating only 76 pampered passengers. Explore the Baltic, far beyond the traditional tourist routes, where large ships cannot navigate.

SEE THE WORLD THROUGH AN EDUCATED EYE.

To see the world is one thing, but appreciating its treasures is something else.

That something else is a Swan Hellenic Art Treasure Tour. Each unique tour is accompanied by a guest lecturer, an expert whose informative talks will bring a deeper awareness and appreciation of the art, architecture, history and natural beauty you will encounter on your tour.

And what tours to choose from. Swan Hellenic Art Treasure Tours cover the world. From Britain's heritage to Europe's history beauty of Latin America. From the Middle East to Australia. Even the rich treasures of India and the Orient. With over 140 departures to choose from, we're sure you'll find at least one that will particularly delight you.

For further information about Swan Hellenic Art Treasure Tours see your Travel Agent or write Exprinter for a free colorful brochure.

Join us for a deeper appreciation of the world's treasures.

The Living End

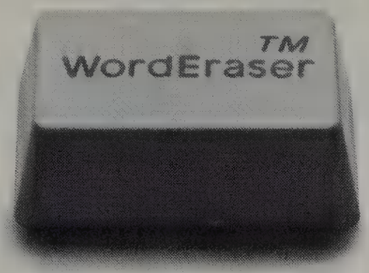
"A gremlin?" asked one observer. Another, noting the milky blue, thought of eyes. But entomologist Tom Eisner put an end to such foolishness. "It's a cockroach," he said. "A rear end shot."

Eisner explained how he obtained this dorsal fixation. "At the Archbold Biological Station in central Florida, you stay in cottages," he said, "and most of them have cockroaches. I consider them the majority group. This one crawled out onto the table where I was working. It was about an inch and a half long. I put some banana down on a piece of cardboard, and when it started to eat, I picked it up gently and carried it to the microscope."

It was a male *Periplaneta australasiae*, the Australian cockroach, and Eisner was particularly interested in the white, sugary looking substance on its posterior. "The white is a protei aceous slime," Eisner said. "It's like mucus, but it's very stick and also slippery. For an ant or spider that tries to grab bac there, it's a disaster. It would be like a person grabbing a gia tube of Duco cement."

Eisner took the shot at 3X magnification with a photoma roscope. The two blue semicircles (colored by the lighting) a the last two segments of the cockroach, which are both covere with the slime. The "ears" are cerci, or feelers, which are like pair of rear antennae. The tiny hairs on them can detect a movement—any sense of trouble approaching and the roac takes off.

Photograph by Tom Eisner



The Word Eraser! The Eraser!

Introducing WordEraser for mistake-proof typing by Smith-Corona.

The word is out! Smith-Corona has just revolutionized erasing. With one button. The incredible WordEraser™ correction. It untypes whole words at a touch.

No skip ping. No c-o-u-n-t-i-n-g. N oovershooting. And that's not all. The WordEraser even lets you type in your new word while it untypes the old one. Amazing is the word for it. And only Smith-Corona has it.

The WordEraser. Another of the many technological advancements pioneered by Smith-Corona. Make no mistake about it.

SMITH CORONA™

Explore the Magnificent Maldives and Seychelles

Experience Salen Lindblad's Expedition Cruising. It's Five Star adventure exploring the little known travel gems.

This February, escape winter and explore the tiny string of islands among the most remote, most beautiful in the world. See villages formed from the white coral mined from breathtakingly beautiful seas. And villages with traditions centuries old. Your vessel is the newly refurbished Ambassador, and Salen's zodiac landing craft take you face to face with the area's incredible natural treasures.

Additional Read

Laxton (p. 42)

Few books or articles about Laxt have been published, and those that ha been are not readily available in this cou try. Some general accounts, however, pr vide a useful framework for understan ing the history of the village. For examp Richard Muir has written a great de about Britain's landscapes and towns, i cluding *The English Village* (New Yor Thames and Hudson, 1980), which boas lots of fine color photographs and d cusses towns like Laxton. Originally pu lished in the 1930s, *The Open Fields,* the husband-and-wife team of C.S. Orw and C.S. Orwin (Oxford: The Clarend Press, 1967), is the only book entire about Laxton. Complete and we documented, it is considered the standa work on the village. George C. Homans *English Villages of the Thirteenth Ce tury* (New York: Russell and Russe 1960) summarizes everyday life in med eval rural England, emphasizing the fie system, ways of working the land, ar what it was like to live on a manor. Th December 1980 issue of *The East Mi land Geographer* (vol. 7, part 6) is devote entirely to the open-field village Laxton. Write to the Department of G ography, University of Nottingham, No tingham, England NG7 2RD for more i formation about this publication. Finall *Laxton: An English Village* is a colo sound filmstrip that comes with an i structor's guide. About twenty copies a available from Donald Donihue, 203 We Wakefield Blvd., Winsted, CT 06098.

Siblicide (p. 54)

The research described in this article presented in greater detail in the March i sue of the *American Naturalist:* see Dou las W. Mock's "Siblicidal Brood Redu tion: The Prey-Size Hypothesis." Mock "Siblicidal Aggression and Resourc Monopolization in Birds," a more tech nical account of his experiment using fo ter parent birds, appeared in *Science* (vo 225, pp. 731–33). Stephen Jay Gould de scribes siblicide in a group of blue-foote boobies in the Galápagos Islands in "Th Guano Ring" (*Natural History,* Januar 1982, pp. 12–19). Mock's "Infanticid

blicide, and Avian Nestling Mortality" *Infanticide: Comparative and Evolu-nary Perspectives,* edited by Glenn usfater and Sarah Blaffer Hrdy, re-ws siblicide and brood reduction in all ds. The book discusses infanticide in a de range of animals, including fish, am-ibians, and primates.

rcupines (p. 62)

Although from time to time a short arti- appears on porcupines, few good, sub-ntial articles have been written about em for the popular audience. Two of the tter ones are "Porcupines" by J. C. cLaughlin (*Country Journal,* January 82, pp. 56–61) and "Equipped for Sur-al," by David Strohm (*National Wild-e,* October-November 1975, pp. 18–). The standard reference books on mmals contain short but accurate ac-unts; the best of these are in *Walker's ammals of the World,* by Ronald M. owak and John L. Paradiso (Baltimore: e Johns Hopkins University Press, 83), and in *Wild Mammals of North nerica,* edited by Joseph A. Chapman d George A. Feldhamer (Baltimore: e Johns Hopkins University Press, 82), which contains pertinent informa-n about the animal presented for a lay-an audience. Finally, both *Herbivores:*

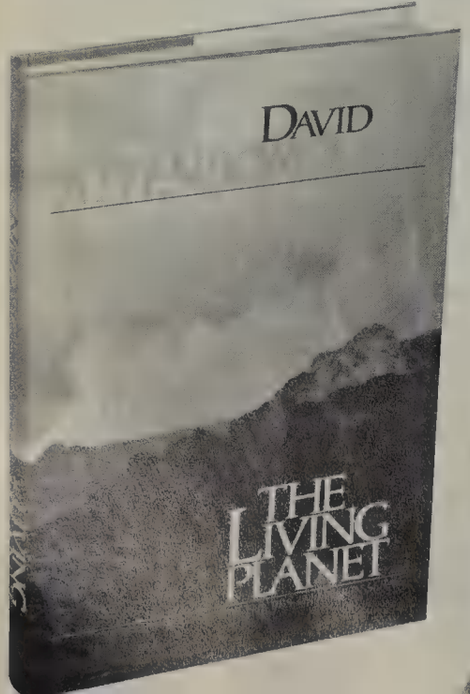
Members' Book Program American Museum of Natural History
Central Park West at 79th Street, New York, NY 10024



r Interaction with Secondary Plant abolites, by G.A. Rosenthal and Dan- H. Janzen (New York: Academic s, 1979), and *Variable Plants and bivores in Natural and Managed Sys-*, edited by Robert F. Denno and k S. McClure (New York: Academic s, 1983), discuss plant defenses nst herbivores.

ination by Rodents (p. 70)

he Principles of Pollination Ecology, K. Faegri and L. van der Pijl (New c: Pergamon Press, 1979, third edi-), is a comprehensive survey of the nical problems of pollination ecology roached from both a theoretical and ctical viewpoint. Introductory chap- review technical problems and draw parisons with spore dissemination in otograms (plants that bear no flowers seeds but propagate by means of es) and pollination in gymnosperms d plants whose ovules are borne on n scales). Following chapters deal with ination of angiosperms (flowering nts) and are divided into three parts: or- s involved in pollination, flower types, pollinator activities. B.J.D. Meeuse, nor of *The Story of Pollination* (New k: Ronald Press Co., 1961), says his k was written "for young persons be- en the ages of eight and eighty (and er)" and advises that "a sense of po- " will help "recapture the mood of dhood's constant wondering" about natural world. Meeuse, whose wonder- began while growing up in the "tropi- paradise" of West Java, has succeeded riting one of the best books on pollina- for nonscientists. He begins by pre- ting a number of principles concerning relationships between flowers and the mals that pollinate them; chapters in section look at the color vision of ani- ls, the ways in which flowers produce ir color effects, and the"honey guides" t lead pollinators to hidden nectar. He n proceeds to chapters on the most im- tant pollinators—bees, birds, butter- s, hawkmoths, flies, bats, and beetles. ry S. Perceval's *Floral Biology* (New k: Pergamon Press, 1965) is also writ- simply, with a minimum of technical ms. Perceval explores why pollination ecessary; the biology of flower parts; ncies of pollination, natural and ani- l; animal food in flowers, pollen, and tar; pollination by birds and insects l features of flowers pollinated by m; isolating and safeguard mecha- ms in flowers; and simple techniques l instruments for observing pollination rself.

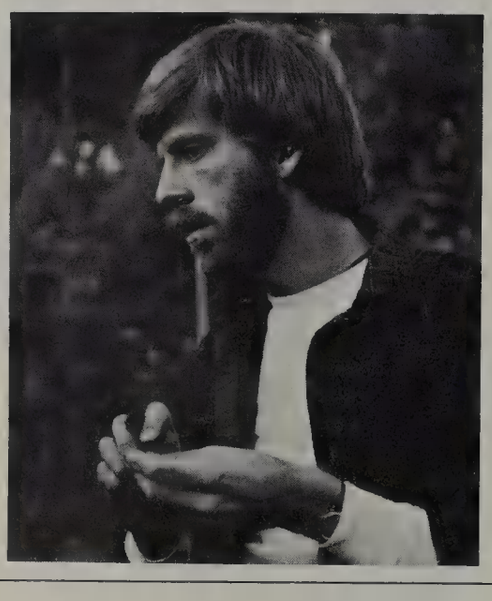
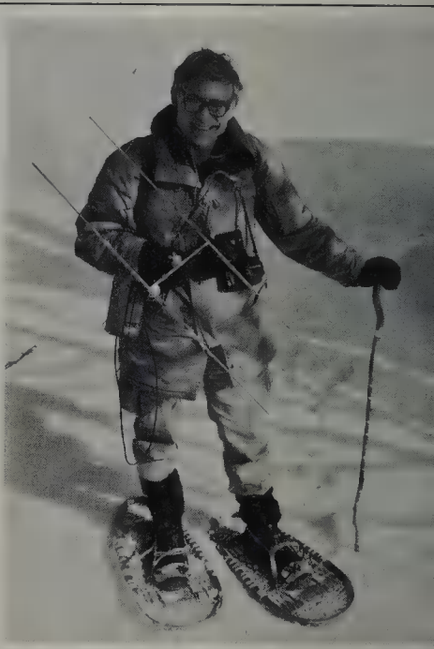
"Growing up in the San Joaquin Valley in California gave me an early appreciation for the native values of rural life," says **Donald D. Donihue** (page 42). "I was first introduced to the English village of Laxton while watching a documentary film entitled *The Medieval Village*." That was in 1970. For the next ten years, the film and its subject matter were "grist for the mill" in Donihue's sociology classes. In 1984, Donihue received a grant from the Exxon Education Foundation to produce a sound, color filmstrip about Laxton. Donihue is professor of sociology at Mattatuck Community College in Waterbury, Connecticut. He is now researching the history and social structure of a small community on Saint Kilda in the Outer Hebrides.

On a field trip to Texas six years ago to study monogamy in egret colonies, **Douglas W. Mock** (p. 54) learned that sibling rivalry among these birds was often fatal. That discovery led him to shift the focus of his research to avian siblicide. During the past fifteen years Mock has done fieldwork on a variety of birds in Minnesota, Oklahoma, Mexico, Venezuela, Panama, South Africa, and Quebec. He is currently on sabbatical from his position as associate professor of zoology at the University of Oklahoma. The youngest of four siblings, Mock says that has nothing to do with his interest in avian sibling rivalry.





Some scientists tie their interest their field of study to a season in ch hood; for others the interest popped later, perhaps under the steady influe of a teacher in graduate school. rarely can they do what **Uldis Roze** 62) can do—tell you the date and moment that they knew their work. was December 4 that I started with porcupines," Roze says. "Decembe 1978." It was the morning after the w ter's first big snowfall and Roze, com out of his cabin in the Catskills, saw mal tracks everywhere. He wande outside until he came upon a fat, w trail slithering off into the woods. It a porcupine trail—he knew that mu And spontaneously, he started follow it, across a stream, through a marsh a and then uphill. The animal's trail w along for a mile, occasionally pulling by hollow trees—it's looking for a d Roze realized excitedly—and then e ing at a big sugar maple with a twis crown. That was it. But somewh along the walk, watching and imagin the animal, admiring its persisten Roze had realized that he was going study this creature. Until then, U Roze was basically a lab man, trained pharmacology. But for the past six ye he has been following porcupines in Catskills, studying their ecology in forest and other topics. Roze teaches Queens College in New York.

"From my earliest recollections, I was interested in nature," says **Delbert Wiens** (p. 70). "All through school and for my first two years in college, I wanted to be a forester. But when I was a junior in college, I met a professor who talked me into going to graduate school and becoming a biologist." Wiens earned a Ph.D in botany at Claremont Graduate School in California with a thesis on the classification and chromosome relationship of mistletoes. Although he is well aware of the plant's folkloric aspects, the internal structure is what intrigues Wiens. "Mistletoe has beautiful chromosomes," he states. A professor of biology at the University of Utah, Wiens is now coauthoring a book on African mistletoe.

This Volkswagen will fit only 1500 people.

There's certainly no shortage of space inside the Limited Edition Wolfsburg Vanagon. (So it's ideal for carrying people and things around town during the week.) There's also a pop-up roof, seating for 6 and two double beds. (So it's ideal for carrying people and things out of town on weekends.) Even the icebox is neatly tucked away behind the front passenger seat.

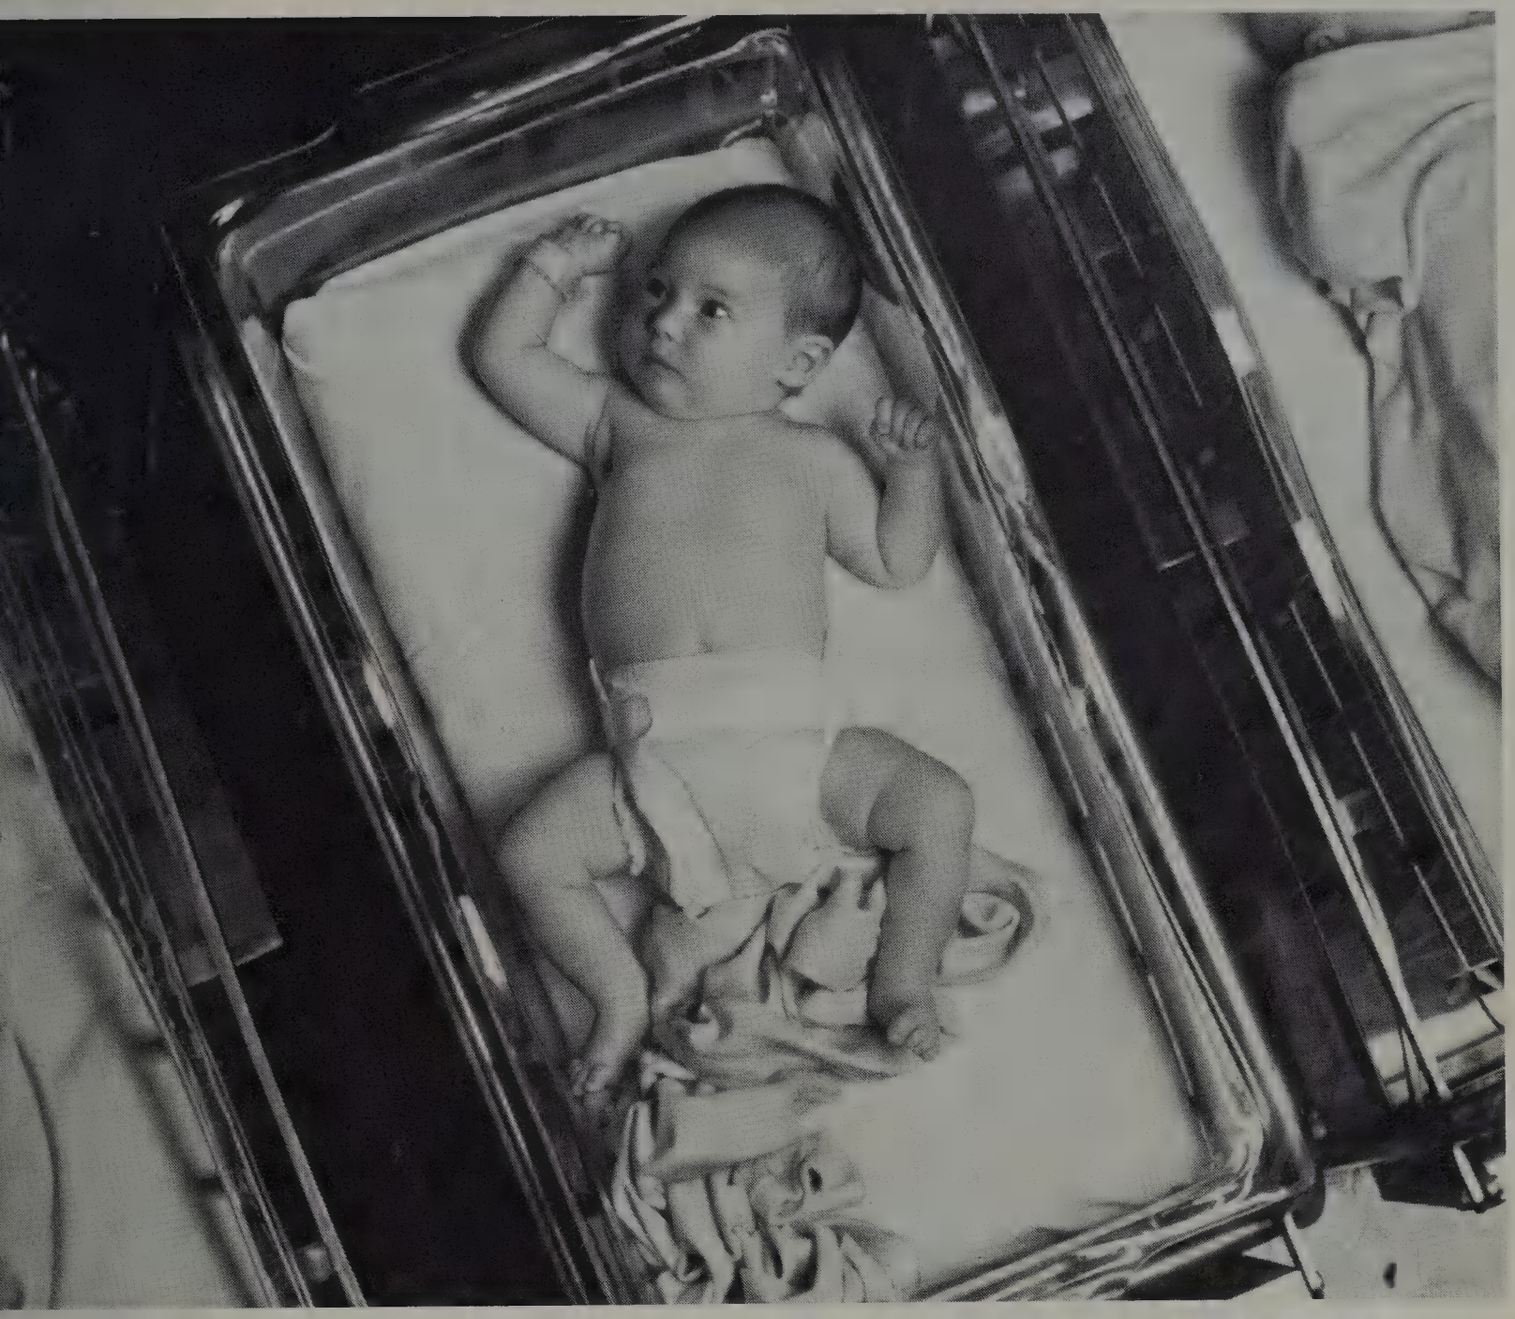
But keep in mind that this German-engineered, German-built Wolfsburg Vanagon is a limited edition. So limited, that there's only enough to fit you. And 1,499 other lucky people.

The 1985 Wolfsburg Limited Edition Vanagon.

It's not a car. It's a Volkswagen.

Seatbelts save lives.

For details call 1-800-85-VOLKS. The Limited Edition Wolfsburg Vanagon is covered by the new Volkswagen 2-year Unlimited-mileage Protection Plan: 2-year unlimited-mileage, limited warranty on entire car, except tires; 3-year unlimited-mileage, limited warranty on corrosion perforation.



WHO'S GOING TO PAY OFF OUR NATIONAL DEBT?

Future generations may be in for a rude awakening. They might have to pick up the tab for this generation's trillion dollar debt.

Stories like this are complex. That's why you should watch The MacNeil/Lehrer NewsHour every weeknight. News stories get the time they deserve. The time *you* deserve. You get more facts. You hear different sides. Most important, you get the analysis you need to understand the issues behind the stories.

Major funding for The MacNeil/Lehrer NewsHour is provided by AT&T, the national corporate underwriter.

Rain Forest Villains

James D. Nations's essay ("Bearing Witness," March 1985) and Gertrude Blom's photographs were indeed effective at arousing anguish and indignation at the destruction of the Selva Lacandona and of the Lacandones, but laying the blame on greedy businessmen diverts us from our own complicity as beneficiaries of industrial civilization. How many of us lay our copies of *Natural History* down on our mahogany coffee tables and bemoan the loss of tropical rain forests? How many of us, to preserve a wild ecosystem, would give up all manufactured articles and live by hunting with bow and arrow? Can we expect the Lacandones to choose differently?

PETER SUNDT
Klondyke, Arizona

I read "Bearing Witness" with great interest. Certainly, the destruction of tropical rain forests, occurring throughout the entire world at an ever increasing rate, should be of concern to every educated person. But Nations neglects to mention that most of this destruction is being caused, not by an increase in population, but by policies originated by such entities as the International Monetary Fund and the World Bank. The World Bank, for example, has strongly encouraged the destruction of the Amazon rain forest by financing the building of highways and mines through equatorial Brazil. Nearly two centuries ago, President Jefferson asserted, "I truly believe that banking establishments are more dangerous than standing armies," and it is easy to see the truth of his observations even today.

A Viper's Striking Distance

Reading Robert K. Colwell's account of a *Bothrops atrox* bite ("A Naturalist at Large," April 1985) brought to mind an encounter I had in June 1984 with a conspecific in Trinidad. In four visits to the island I have seen six specimens of *B. atrox* (called *mapepire balsain* on Trinidad), and with one exception, all were living close to human settlements. On an overnight hiking trip into the forest of the northern range I collected, photographed, and released without incident a specimen close to five feet in length. Several days later I was driving late at night in search of amphibians and reptiles. A small, two-foot specimen was stretched out on a wet blacktop road. Upon first examination, my companions believed it to have been hit by a passing car. However, when I slid a snake hook under its body, the snake began to move. For forty-five to sixty seconds I tried to direct it into an open bag, but the snake successfully avoided capture. It then did something totally unexpected. It was suddenly airborne toward me. A few backward steps and I was out of the snake's trajectory, but it was a full twenty-four to thirty inches off the pavement with its body parallel to the ground. I should point out here that the road was flat and the snake was not on an incline. The snake was soon bagged and was not examined until the following day. When it was removed from the bag the snake was dead; it had apparently been injured by a passing car before we found it.

There are sixty-one species of *Bothrops*. Several have the habit of jumping during a strike, but this behavior has not been well documented in *B. atrox*. Had the specimen I photographed a few days before performed a defensive leap, my experience could have been like Colwell's. *B. atrox* is widespread in the forests of South America, and naturalists would be well advised not to underestimate the striking distance of this species.

Irish Corn and Haitian Breadfruit

In "The Great Breadfruit Scheme" (March 1985), Gerald and Selmaree Oster assert that in 1845, many Irish tenant farmers chose to starve rather than a
cept a British offer of maize to replace p
tatoes in their diet. This point wa
introduced by the authors to buttress the
assertion that Haitian slaves rejecte
breadfruit as a food because it was assoc
ated with their servile status in a strang
land. Since Irish tenant farmers were als
exploited, their refusal to accept maiz
would have been analogous to distaste fo
breadfruit among Haitian slaves. Hov
ever, no such rejection took place in Ir
land. The British offer of maize was mad
only halfheartedly, to say the least.

Cecil Woodham-Smith's *The Gre
Hunger* is an authoritative source on th
Irish famine of 1845–49. Woodham
Smith reports that in the spring of 184
after an initial period of resistance to th
strange new food, maize became im
mensely popular in the areas where it wa
available. Subsequently, difficulties i
transportation, storage, and milling, a
well as continued government refusal t
sponsor an adequate relief effort, kep
maize from reaching the starving masse
in rural western Ireland. In later year
when maize was somewhat more plentifu
many impoverished rural people were un
able to afford it even at low prices, sinc
they had virtually no income at all. Fear
ful of encouraging indolence, the govern
ment discouraged free distribution o
maize.

The millions who starved or were force
to emigrate from Ireland in the late 1840
did not do so because of distaste for maize
but because no significant relief effort wa
mounted when the harvest of their staple
the potato, was destroyed by blights.

THOMAS TILITZ
Jackson Heights, New York

In an otherwise interesting and infor
mative article, I was astounded to read
"To cultivate these cash crops profitably
slave labor was needed...." After al
these centuries, do we still have to take up
arms against this outrageous institution

Just a word about the price of The Glenlivet. Preposterous.

Is the premium we place on The Glenlivet really so outlandish? No more so than the premium placed on great vintage wines and fine champagne cognacs. The reason? Taste. Just one sip and you'll know that The Glenlivet has a taste that's without equal.

The Glenlivet is Scotland's first and finest single malt Scotch, from Scotland's oldest licensed distillery. And, just as it always has been, this 100% Highland malt whisky is distilled from natural spring water and fine malt barley, then aged in oaken casks.

Only The Glenlivet's time-honored methods can achieve this unequaled taste. A taste that sets us apart. Its smoothness, body and bouquet are qualities found only in this unique Scotch.

Of course, some people may still insist that The Glenlivet is too expensive. We have just one word to say about that. Preposterous!

The Glenlivet

12-year-old unblended Scotch.
About $20 the bottle.

Mass Extinctions and Opportunistic Survivors

Norman Myers ("The End of the Lines," February 1985) warns us that the creatures emerging from the swift annihilation of species that mankind is now perpetrating are likely to be "opportunistic," "clever," "generalist" species that adapt to a wide range of environments, multiply rapidly, and "often become pests. Examples include the English sparrow, the European starling, the housefly, the rabbit, the rat, plus many 'weed' plants." It is unfortunate that Myers failed to follow this thought to its proper conclusion: namely, that the species that will thrive *after* the coming mass extinctions may include one or more that are modeled on *Homo sapiens*—certainly the most opportunistic, clever, and generalist creature known to zoology and quite possibly the worst pest this planet will ever see.

ROBERT SCHMID
Hanover, New Hampshire

It seems to me that Norman Myers and others grant too much power to the human species to prevent the coming catastrophe. Myers demonstrates that Earth can only support a finite number of individuals in each ecological niche. To free all the niches that are impacted most severely, humans and those species we have chosen as our food and our pets would have to be reduced in numbers greater than birth control alone will accomplish. Is Myers suggesting that we should be willing to take such drastic measures to maintain the richness of species our current era enjoys?

If not, we must accept that the loss of some of the species we know today is inevitable. This is not to say that we should continue in our wanton ways, but rather that we should realize that our best efforts will not be enough to indefinitely preserve species that are already on their way out.

The Clock of Evolution Needs Repair

Perhaps the reason that no one aside from Stephen Jay Gould ("This View of Life," April 1985) is proclaiming the message that molecular biology has solved *the* problem of the ages is because such is in fact not the case. For DNA hybridization distances to form an evolutionary clock they would have to be both additive and clocklike. They generally are not: Bonner, Heinemann, and Todaro showed that suc distances are not clocklike in lemurs ve sus other primates (*Nature*, 1980). As f additivity, Farris, in *Advances in Cl distics* (1981) and in *Cladistics* (1985 showed that molecular sequence diffe ences are not additive. As DNA hybri ization distances supposedly measure s quence differences, they are not additiv either. Since the premises underlying th method are incorrect, it has scarcely sep rated homology and analogy. Phylogen ticists do well to regard trees based upo such distances skeptically.

JAMES M. CARPENTE
Assistant Professor of Biolog and Assistant Curator in Entomolog Harvard Universi Cambridge, Massachuset

Stephen Jay Gould replies:

My esteemed colleague from upstai has not grasped the message of those wh labor in the bowels of his building. "*Th* problem of the ages," to which I referre in my column, cannot be the constructio of an "evolutionary clock," as Carpente asserts herein. After all, biologists befor 1859 were not evolutionists, but I do no exclude them from "the *ages*." My artic identified the central problem as th establishment of proper "relationships among organisms (identified as genealog cal since 1859, but attributed to a host o other reasons before). DNA phylogenie can, for the reasons I cited, determin these relationships by properly sorting ho mology from analogy for the first tim Whether or not these molecular distance form a clock is an interesting questio awaiting resolution, but not "the proble of the ages." In fact, my article was explic itly agnostic on this point. I ventured hope that the clock might work, but state that current evidence is far from conclu sive.

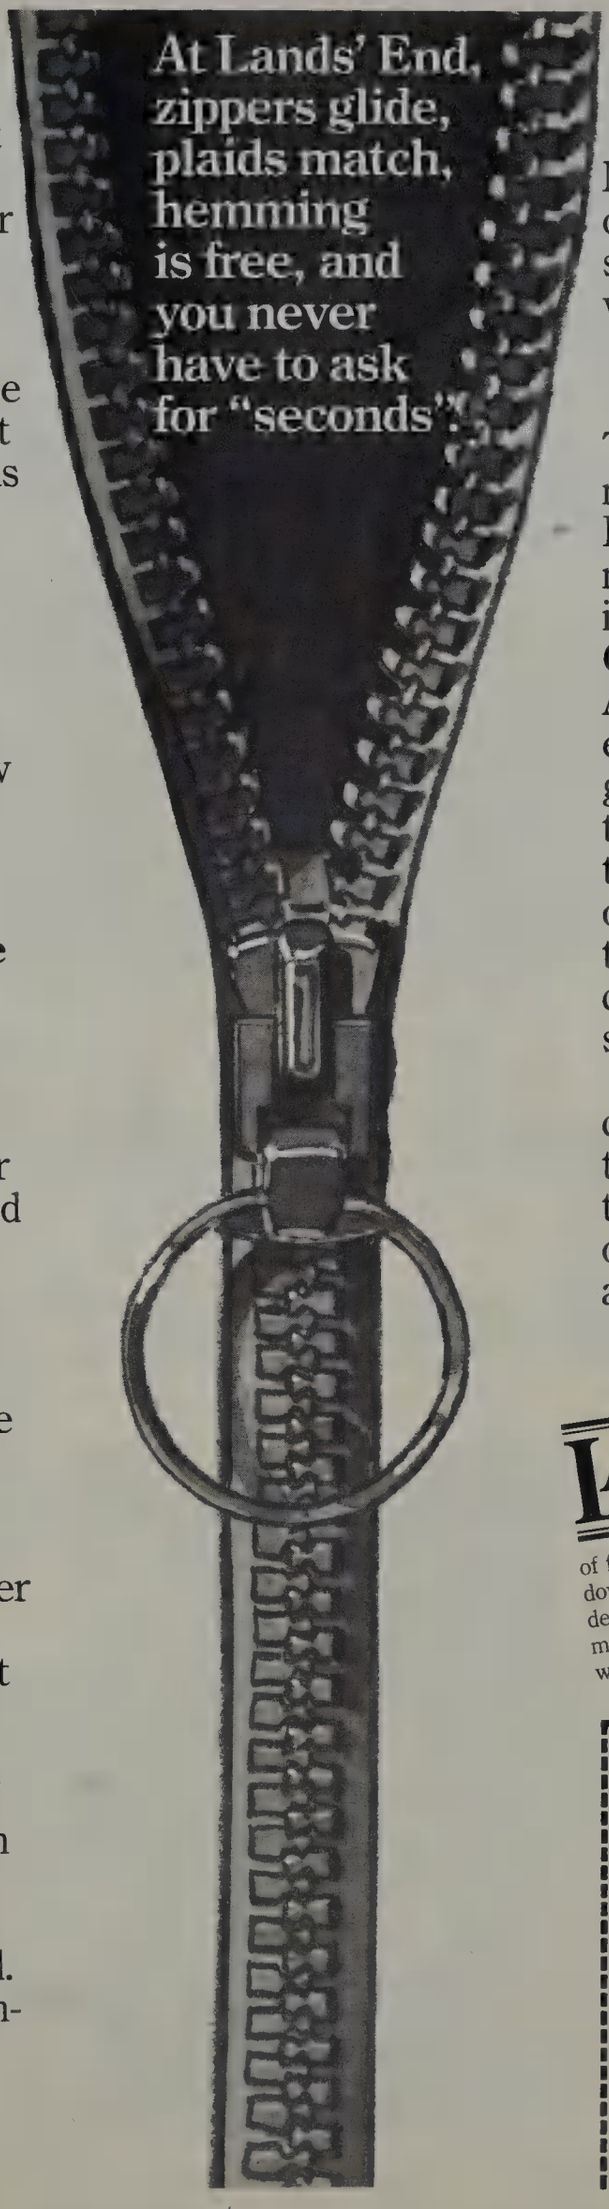
Baretta and William Blake

Look at page 71 of your March issue fo a second: ". . . a vision by Robert Blake' Robert? You mean Baretta? William brother possibly?

NANCY FERNANDE
New York, New Yor

Victor Scheffer and the editors meant, o course, William Blake, English poe painter, and engraver (1757–1827).

Erratum: On page 26 of our April 1985 i sue, the word *photographs* was inadve tently substituted for the word *portrait* giving the impression that George Catli (1796–1872) was a photographer rathe than a painter.



We take the position that you should never be left at the mercy of a broken collar button on a buttondown shirt.

And on a shirt you buy from us, you aren't. Because with every Lands' End shirt we tuck in extra buttons. As long as someone in the house can thread a needle, you're home free.

Same with shoes. With every pair of tie shoes, we throw in an extra pair of laces. And who do you know besides Lands' End who sends along extra yarn to mend a sweater?

We practice preventive maintenance, too.

The YKK zipper is a prime example. We use this marvelous zipper in all of our soft luggage, because as far as we have ever determined it offers the ultimate in quality, ease of operation, and virtual immunity to damage. This is worth knowing when you take one of our bags skiing, or on a boat, or on a week-long business trip.

The YKK zipper is bigger than most. Still, it also manages to be attractive. It has a large, round pull that runs free, a metal slide of baked enamel, and a nylon/cotton zipper tape on which it travels. The auto-lock slide makes sure your bag stays closed when it should.

We could use less expensive zippers and you might not notice. But we would. And we're determined not to compromise on quality.

So, on zippers, it's YKK. Nothing less. And in every other respect—large or small—*quality* is our watch word. We guarantee it.

Let's review that guarantee.

The Lands' End guarantee may be the world's shortest. It is certainly the world's most unconditional. We say it in two words. GUARANTEED. PERIOD. And because we guarantee everything—from soft luggage, to shoes, to clothing, to accessories—we see to it that plaid matches plaid in our sport shirts; that trousers are hemmed free of charge; and that our luggage seams are bound and welted.

Send for one of our free catalogs, and as you leaf through its pages, think of these things. Better still, call our toll-free number 24 hours a day. That's 800-356-4444.

LANDS' END®
DIRECT MERCHANTS

of fine wool and cotton sweaters, Oxford button-down shirts, traditional dress clothing, snow wear, deck wear, original Lands' End soft luggage and a multitude of other quality goods from around the world.

Bluebird Belligerence

Ferocious fights between female eastern bluebirds may signal a clash of maternal strategies

by Patricia Adair Gowaty

A European colleague of mine recently called eastern bluebirds (*Sialia sialis*) the North American symbol of harmonious family life. Another writer has called them the most gentle and pacific of creatures. But despite their reputation for harmony and peace, my research indicates that bluebirds are often belligerent to individuals of other species as well as to other bluebirds. Aggression between bluebirds can be violent and dramatic, and what surprises many observers is that females are often fiercer fighters than males. Two, perhaps unrelated, questions—why females fight and why female aggression surprises theoreticians—interested me.

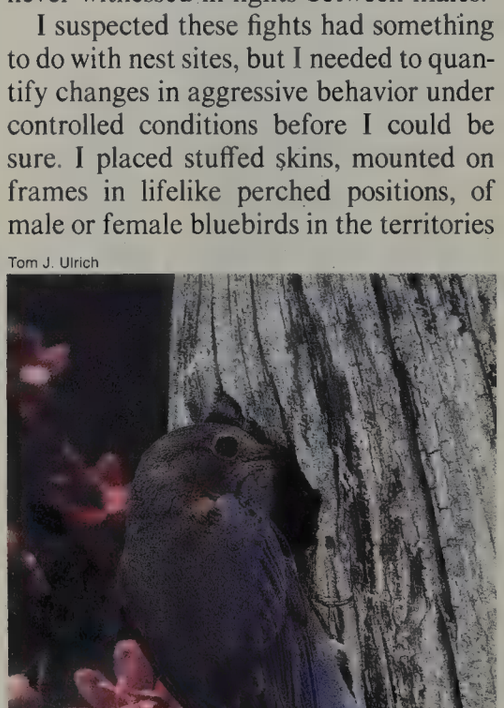
Bluebirds nest in cavities, and since the introduction and proliferation in North America of European starlings and house sparrows, which compete with bluebirds for nesting and roosting holes, eastern bluebirds have done almost all of their nesting in boxes built specifically for them. Most bluebird fights I have seen, whether with house sparrows or other bluebirds, seem related to this limited resource.

Like 90 percent of other bird species, bluebirds are sociographically monogamous—that is, one male and one female seem to interact primarily with each other, but their absolute fidelity cannot be confirmed. I studied bluebirds in northwestern South Carolina on 27,000 acres of farmland owned by Clemson University. In more than 95 percent of the 833 nesting attempts I observed, one male nested with one female. Females build nests and incubate the eggs, but the males—as in many songbird species—help feed the nestlings and fledglings. Both sexes defend their territory from other birds and guard against predators, but conflict between members of a pair is rare.

In early spring, males sing and chase away male territorial intruders. These chases sometimes end in attacks in which the birds grabble with their feet and flail at one another with their wings as they topple to the ground. Resident females that have procured nesting cavities also fight with female interlopers at this time. Females fight less often than males, but their battles are sometimes more fierce. I have seen female bluebirds maim and even kill each other, outcomes I have never witnessed in fights between males.

I suspected these fights had something to do with nest sites, but I needed to quantify changes in aggressive behavior under controlled conditions before I could be sure. I placed stuffed skins, mounted on frames in lifelike perched positions, of male or female bluebirds in the territories

Tom J. Ulrich



A female eastern bluebird

of breeding bluebirds. I counted all the reactions of the birds—physical attacks, dive-bombings, and vocalizations—for ten minutes. Later I compared frequencies of these actions in each stage of the nesting cycle—nest building and egg laying, incubation, and feeding of nestlings.

I found that male bluebirds are most aggressive to male interlopers (both living birds and models) during the nest building and egg laying stages. Male-to-male aggression tapers off during incubation and is almost nonexistent when nestlings are being fed. Even when nest building and egg laying occurred in June and July (relatively late), males were still belligerent, indicating that the change of season is not a cue to alter aggressiveness. And since I had presented the model to any pair only once during the season, I knew that the decrease in aggressiveness during the nesting cycle was not due simply to habituation to the models.

These observations left me with two evolutionary explanations for male-to-male aggression. First, a male might be guarding his mate, preventing her from copulating with another male. Such mate guarding is adaptive if it protects males from investing parental effort in another male's offspring. The mate-guarding explanation fits neatly with the evidence. Aggression hits a peak during nest building and egg laying, the times when copulations will produce offspring. Alternatively, aggressive bluebirds might be guarding their valuable nest sites, an adaptive behavior if—as I think is the case—bluebirds seldom or never breed successfully without access to nesting cavities. Cavity guarding would also explain the peak in aggression during nest building and egg laying, because nest sites are

A miserable reason to own a Subaru wagon.

The new Subaru front or 'On Demand' four wheel drive Wagon can handle just about any miserable condition Mother Nature dishes out.

What's more, there are also beautiful reasons to own one. Like new aerodynamic styling. A larger interior. 25% more cargo space. And a wide choice of transmissions and engines including turbo and fuel injection.

Now we realize that's a lot of reasons to buy a wagon but if there weren't so many reasons to buy it, it wouldn't be a Subaru.

THE 1985 SUBARU

Inexpensive. And built to stay that way.

Seat belts save lives.

Introducing...

Dolls of the World

A fascinating collection of porcelain collector dolls, each portraying the traditional dress of a different country of the world.

FRANCE
Brigitte

Shown actual size.

©DM

Shown smaller than actual size of 8½" in height.

nagine a collection of porcelain dolls, each one authentically ortraying the traditional dress of a different country. Picture a llection in which each porcelain doll is unique, not only in ess but also in facial appearance. Imagine a collection you an buy today that is crafted with the same care that the great th century dollmakers lavished on their creations.

An impossible dream? No! The Danbury Mint proudly presents *olls of the World.*

Hand-painted bisque porcelain . . . like the legendary dolls of old

collectors of antique dolls, doll-making reached its peak in th century France. Some of the great French dolls of the 1800's ave sold for thousands of dollars.

Dolls of the World will be crafted with the same care as those gendary dolls of long ago. Head, arms, and legs will be made of pported bisque porcelain. Facial features will be sculptured for delicate look and feel, and painted by hand. What's more, *each ll's head will be a different original sculpture*—the facial appear- nce of each will capture the special personality of its homeland.

Each doll's costume individually hand-tailored

ach young girl's costume will be individually hand-tailored. As ppropriate, costumes will feature elegant embroidery, exqui- te lacework, and fascinating fabrics with different weaves, xtures and colors. Each doll will be distinctively dressed from ead to toe – in a generous eight and one-half inch size. Each oung girl will have a personality of her own, which reflects the ountry she represents.

There's *Brigitte,* of France, attired in traditional dress that fea- res a ruffled bonnet, lovely pinafore and a dress with elegant cework. *Carmen,* of Spain, will wear a bright red dress with ffled flounces as well as a matching *serape.*

Suisan, of Scotland, will be clad in a traditional tartan kilt and ighland hat. *Abigail,* of the United States, will be dressed in the olonial style: a bright red bonnet with matching apron, and a owered dress which she would probably have sewn herself.

Each doll will be accompanied by a display stand

he display stand will allow you to display each lovely doll wher- ver you wish – on a table or a shelf, on a mantle, or in a cabinet ith other prized collectibles.

Each doll will also come with a Certificate of Authenticity bear- g your personal serial number – establishing each doll as part your registered collection.

A remarkable value

These dolls can be obtained only from the Danbury Mint. When you can find dolls of comparable quality and size in stores, you can expect to pay up to $50 each. But the Danbury Mint is able to offer each doll in *Dolls of the World* for only $24.50 – with no extra charge for the stand.

To acquire your collection, simply complete the Reservation Application and return it promptly. You will receive your dolls at the rate of one every month and will be billed separately for each shipment. You may charge each doll to VISA or MasterCard.

Your satisfaction is guaranteed. If you receive a doll you are not satisfied with, you may return it within 30 days for a replacement or refund. You may cancel your subscription at any time.

Act now

Dolls of the World is an incomparable collection which combines everything you could desire: authenticity, exclusivity, meaning, beauty and craftsmanship. Do reserve your collection today!

Male and female bluebirds: "Conflict between members of a pair is rare."

most vulnerable to takeover when few or no eggs or nestlings are present.

The pattern of female-to-female aggression resembled that of males; intense during egg laying, it was almost nonexistent after the eggs had hatched. But explaining this seemingly unusual female-to-female combativeness was more difficult. Perhaps resident females are guarding their nests from intruding females trying to lay eggs. Evidence in support of this hypothesis came from exclusion studies that, though designed to rule out paternity, enabled us to rule out mothers as well. A.A. Karlin (an ecological geneticist now at the University of Arkansas) and I began analyzing blood proteins of bluebirds in my study area to see whether some nestlings were in fact genetically unrelated to the adults caring for them. (The procedure is similar to the one commonly used to rule out human paternity.) Only a very small amount of blood is necessary to perform the test. In a process that seldom took more than five minutes, I captured the birds, bled them, and released them.

We tested blood in twenty-seven bluebird "families," that is, groups of nestlings and adults associating in single nest sites, and found that fully one-quarter of the families showed evidence of unrelatedness between adults and young. This outcome raised a number of questions. Under what circumstances, for instance, would an adult care for an unrelated hatchling? A male might do so if his mate had copulated with another male or if she had incubated the egg of an intruding female already mated to an outside male. When a resident female cares for an unrelated hatchling, there is usually only one explanation: an outside female has managed to lay an egg in the resident's nest. In this case, the resident male may or may not be the father. This second possibility was especially interesting to us because 15 percent of our female birds (but only 5 percent of males) took care of an unrelated nestling.

Could defense against intraspecific nest parasitism be the explanation for female-to-female aggression? I think so. Fights among bluebirds seemed most frequent and intense when nest parasitism was most likely to yield living offspring—when host females were laying eggs. Intraspecific nest parasitism also has been seen among other songbirds, particularly cavity nesters. Does something about nesting in holes predispose these species to high levels of "stolen" parentage? A bluebird cannot simply excavate a nest cavity the way a woodpecker can, and in recent years, starlings and house sparrows have increased the competition over already-made holes. Because bluebird nest sites are in short supply, perhaps the only way some females can successfully reproduce is to be opportunists—to lay their fertile eggs in nests holding some other bluebird mother's eggs.

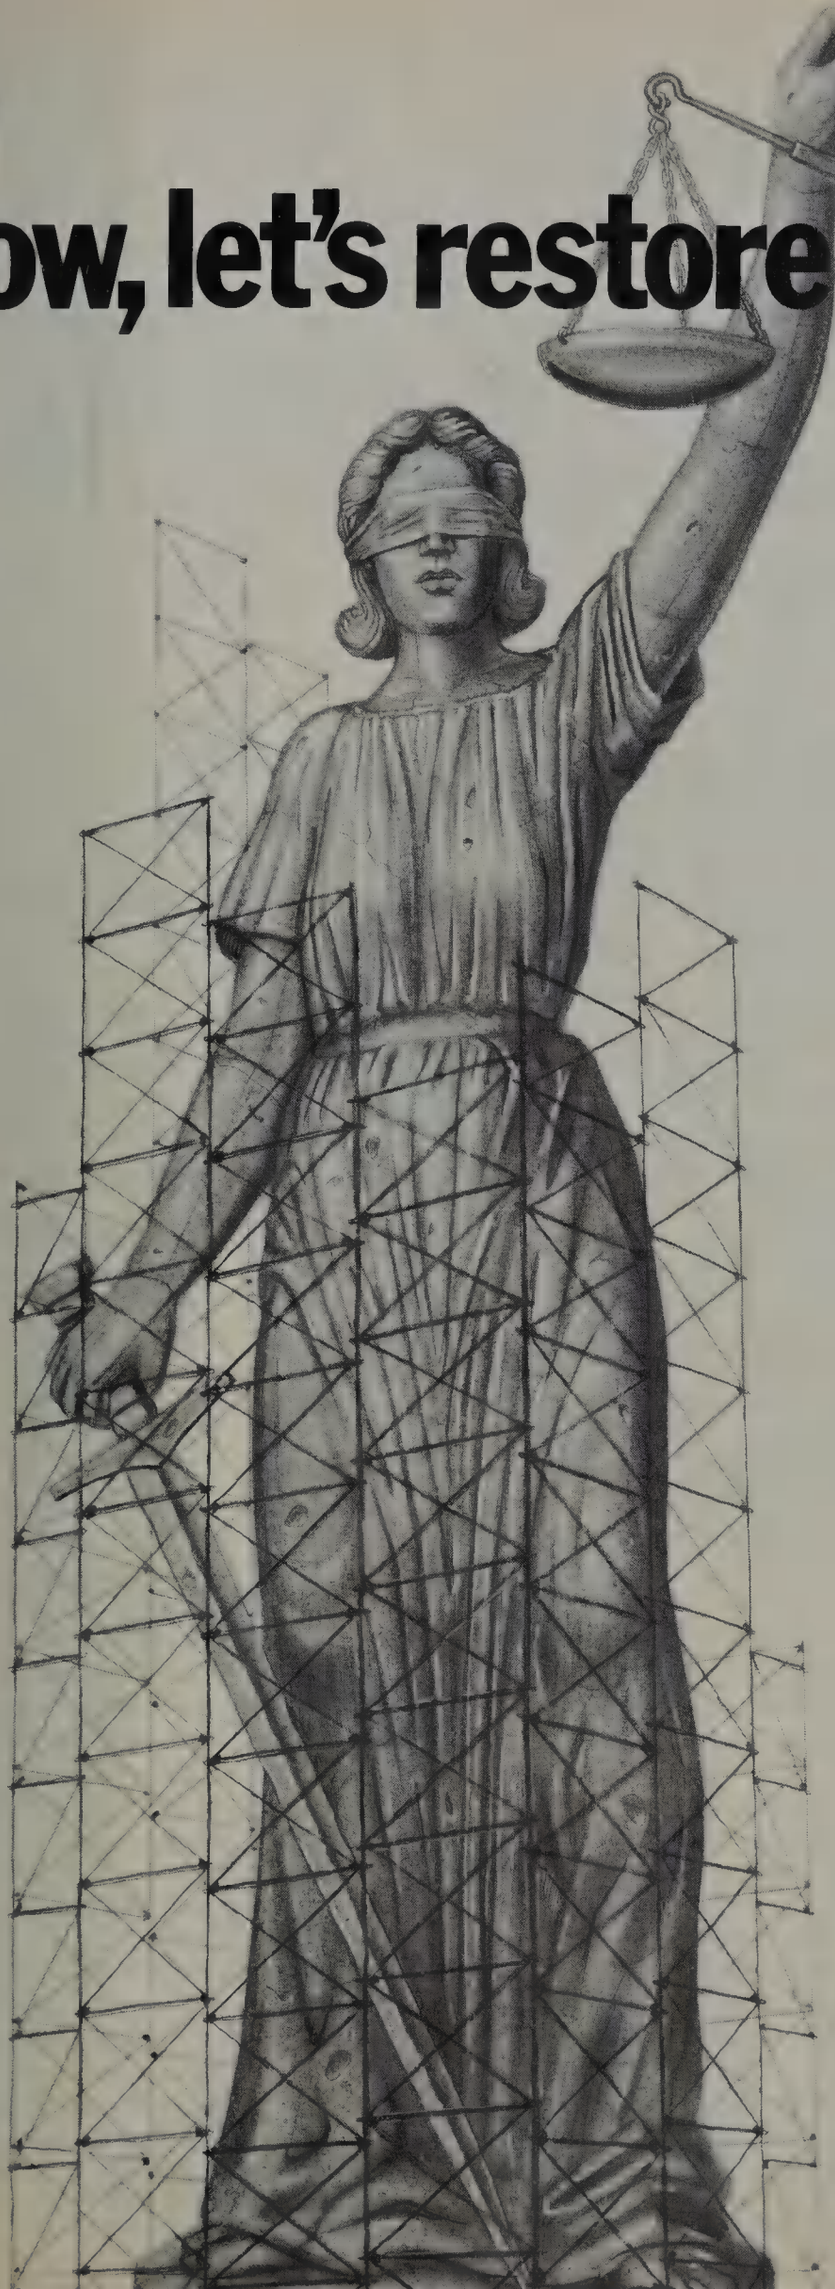
It may also be that cavities and the nests they contain are easy for other birds to find, thus encouraging parasitism. Or it simply may be that ornithologists study cavity nesters more often than they do other birds, and therefore more frequently associate parasitism with cavity nesters.

Another puzzle remains: Why do bluebird fights occur only between individuals of the same sex? Shouldn't males also want to drive off females about to lay an egg already fertilized? One theory suggests that if a male is not aggressive to an intruding female, he may have a later opportunity to mate with her, thereby giving him the evolutionary advantage of producing extra offspring. Laboratory and field data have so far told us little about these possibilities, but I suspect that bluebird mating relationships will prove to be more complex than our theories have led us to believe.

Curiously, ornithologists have only recently begun to study nest parasitism within one species and to ponder its consequence—uncertain maternity. Could it be that we have ignored the potentially strong selective force of alternative female reproductive strategies because we are mammals, animals for which only paternity is questionable?

Patricia Adair Gowaty is research associate/assistant professor in the Department of Biological Sciences at Clemson University.

low, let's restore Civil Justice.



Year after year, our civil justice system has become slower. More costly. Less fair to the very people it was meant to help.

We all pay the price. Some of us pay in the frustration of waiting for a case to end, or by seeing a settlement eaten away by legal costs. All of us pay in the form of higher taxes and insurance premiums.

Experts agree on the urgent need for civil justice repair. Chief Justice Burger has criticized "the high cost of legal services and the slow pace of justice." Derek Bok, president of Harvard and former dean of Harvard Law, has called our legal system "the most expensive in the world."

A 1984 Rand Corporation study of thousands of asbestos-related lawsuits shows how serious the crisis has become. Cases closed took an average two years and eight months, with 11 percent taking six years. How much money went to asbestos victims? Only 37 percent of the expenses and compensation paid by defendants and insurers. The other 63 percent went to pay litigation costs.

Can anything be done? We think it can.

We're the Insurance Information Institute. Our members, property and casualty insurance companies, are vitally involved in this issue. They've joined with others–doctors, lawyers, government officials, business leaders–in coalitions of concerned citizens. Together, they're developing new solutions. In many states, their ideas are being translated into action.

Our latest report, *The Civil Justice Crisis,* examines the reforms now being proposed. It tells how you can get involved. We'd like you to have a copy, free of charge.

Fleeming Jenkin Revisited

This obscure, but able, Victorian gentleman convinced Darwin himself on an important evolutionary point

by Stephen Jay Gould

The European revolutions of 1848 played a pivotal role in several famous lives. Karl Marx, exiled from Germany, published the last issue of his *Neue Rheinische Zeitung* in red, then moved to England, where he constructed *Das Kapital* in the reading room of the British Museum. The young Richard Wagner, espousing an idealistic socialism that he would later reject with vigor, manned the barricades of Dresden, then fled from Germany to avoid a warrant for his arrest and missed the première of *Lohengrin.*

Another man, destined for a lesser but secure reputation, experienced a touch of the same excitement. In February 1848, Henry Charles Fleeming Jenkin, a fourteen-year-old boy from Scotland, found himself in Paris surrounded by rebellion. He wrote to a friend in Edinburgh: "Now then, Frank, what do you think of it? I in a revolution and out all day. Just think, what fun!"

In 1867, the same Fleeming Jenkin would taste revolution of a different kind—this time as a transient participant, not a mere observer. In his much revised fifth edition of the *Origin of Species*, Charles Darwin made a substantial concession by admitting that favorable variations arising in single individuals could not spread through entire populations. (In retrospect, Darwin need not have conceded. He based his admission on a false view of heredity. In a Mendelian world, unknown to Darwin, such favorable variations can spread—see the subsequent discussion. Nonetheless, Darwin's concession represents a small but celebrated incident in the history of evolutionary thought.) Darwin wrote:

> I saw . . . that the preservation in a state of nature of any occasional deviation of structure . . . would be a rare event; and that, if preserved, it would generally be lost by subsequent intercrossing with ordinary individuals. Nevertheless, until reading an able and valuable article in the *North British Review* (1867), I did not appreciate how rarely single variations whether slight or strongly marked could be inherited.

Nearly every book in the history of evolution recounts the tale and refers to the author of this "able and valuable article" as "a Scottish engineer" or, more often, "an obscure Scottish engineer." The author was Fleeming (pronounced Flemming) Jenkin. Darwin, more explicit and vexed in private letters than in public texts, wrote to Joseph Hooker in 1869: "Fleeming Jenkin has given me much trouble. . . . "—and to Alfred Russel Wallace a few days later: "Fleeming Jenkin's arguments have convinced me."

All evolutionists recognize (and mispronounce by excessive literalism) Fleeming Jenkin as the man who forced an explicit, though unnecessary, concession from Darwin, but we know nothing about him and tend to assume he rose from general obscurity for one small moment in our sun—a lamentable parochialism on our part.

My own career has included two fortuitous and peculiar intersections with Fleeming Jenkin—so I decided that I must write a column about him now, before a third encounter elevates coincidence to inescapable pattern. I was an undergraduate at Antioch College from 1958 to 1963. Antioch was (and is) a wonderful school in the finest American tradition of small liberal-arts colleges. But it doesn't boast much in the way of library facilities for scholarship based on original sources. One day in 1960, I was browsing aimlessly through the stacks and found a crumbling run of the *North British Review* for the mid-nineteenth century. I recognized the name from Darwin's citation and my heart skipped a beat as I hoped against hope that the volume for 1867 lay within the series. It did, and I then spent a more anxious minute convinced that I had the wrong title or that the issue for the right month would be missing. It wasn't. I found Jenkin's article and rushed to the pre-Xerox wet processor (anachronistically named smellox by a friend of mine a few years later, in honor of the unpleasant chemical that left its signature even after drying). I fed dimes into the machine and soon had my precious copy of the original Fleeming Jenkin. What a prize I thought I had. I was sure that I possessed the only copy in the whole world. (Can you imagine what one peek at the Harvard library does to such naiveté?) I have carried that copy with me ever since, assigning it to properly Xeroxed offspring to classes now and again, but never dreaming that I would write anything about Jenkin.

Then, last month, I was browsing through a friend's Victorian literature collection, aimlessly running my eye along the titles of Robert Louis Stevenson's complete works. I found *Treasure Island, Kidnapped,* and all the other items of my old "Author's" card game. But my heart skipped another beat at the next title, *Memoir of Fleeming Jenkin.* The "obscure Scottish engineer" had achieved sufficient renown (in areas far from my own parish, where he only dabbled, however successfully) to win a full volume from Stevenson's pen. I kicked myself for sectarian assumptions in the granting of "importance," vowed to learn more about Jenkin (and to tell my fellow evolutionists), and raided the stacks of Widener Library, where I found several copies of Stevenson's memoir, amidst (no doubt) a liberal sprinkling of *North British Re*

views for 1867 (which, *smelloci gratia*, I didn't need).

An interesting man, Fleeming Jenkin—and made all the more appealing by the strength of Stevenson's prose. Jenkin spent most of his life in Edinburgh, where he campaigned for the improvement of home sanitation, conducted some of Britain's first experiments with the phonograph, produced and directed amateur theatricals, hated golf (about as bad as barfing on apple pie in those parts), and became the first professor of engineering at the University of Edinburgh. Most importantly, he was a close friend and colleague of Lord Kelvin and spent most of his career designing and outfitting transoceanic cables with the great physicist.

Stevenson's book has a lovely, archaic charm. It describes a moral perfection that cannot be, and belongs to the genre of guiding homilies based on lives of the great. If Jenkin ever gazed at a woman other than his wife, if he ever raised his voice in anger or acted in even momentary pettiness, we are not told. Instead, we get glimpses of a simpler and formal world based on unquestioned certainties and perhaps better past. In 1877, Jenkin writes to his absent wife about their son: "Frewen had to come up and sit in my room for company last night and I actually kissed him, a thing that has not occurred for years." The Captain, Jenkin's aged father, dies at age eighty-four but achieves solace in his last hour from a false report on the rescue of General "Chinese" Gordon at Khartoum: "He has been waiting with painful interest for news of Gordon and Khartoum; and by great good fortune, a false report reached him that the city was relieved, and the men of Sussex (his old neighbors) had been the first to enter. He sat up in bed and gave three cheers for the Sussex regiment."

Stevenson's memoir contains exactly one line on Jenkin's 1867 foray into evolutionary theory: "He had begun by this time to write. His paper on Darwin . . . had the merit of convincing on one point the philosopher himself." Evidently, Jenkin needed neither evolution nor the *North British Review* to merit Stevenson's extended attention. I felt a bit ashamed at my own previous parochialism. Do grocers know Thomas Jefferson only as the man who invented that thing that gets the cereal boxes down from the top shelf?

The backward reading of history, known to professionals as the Whiggish approach (in dubious honor of those Whig historians who evaluated their predecessors exclusively by their adherence to ideals of Whig politics unknown in their times), has cruelly misserved many fin thinkers, Jenkin included. Several of m essays try to rescue scientists I respec from this mistreatment. Of the grea *Prodromus* of Nicolaus Steno, the found ing document of geology, for example most students learn only that it estab lished the law of the "constancy of interfa cial angles" in crystals. I read the *Prodro mus* a half dozen times and could neve find the reference. Finally, I located th law as a throwaway comment in a figur caption—where it plays no role whateve in the development of Steno's argumen The *Prodromus* is a brilliant taxonomi treatise that establishes rules of reasonin in geology by correctly classifying soli objects found within other solids (crystal in rocks, fossils in strata, for example), an it must be viewed on its own terms an purposes if we wish to understand Steno' genius (see my essay of May 1981).

Jenkin has suffered because commen tators extract from his 1867 article jus the one small point that provoked Dar win's concession—and then analyze it i modern terms by pointing out that a twen tieth-century Darwin could stick to hi Mendelian guns. No modern evolutionar biologist, to my knowledge, has ever con sidered Jenkin's argument as a whole an appreciated its force, despite its errors i modern terms. I shall attempt this rescu but bow first to the constraints of histor and discuss the point that secured Jenkin' slight renown in evolutionary circles.

Darwin and Jenkin accepted the usua notion of heredity prevalent in the times—a concept called blending inher tance. Under blending inheritance, th offspring of two parents tend to lie hal way between for inherited character Jenkin pointed out to Darwin, or so th usual and quite inadequate story goe that blending inheritance would challeng natural selection because any favorabl variant would be swamped out by back breeding with the predominant parenta forms. Jenkin's own example will mak the point clear. It also serves as a sad re minder of the unquestioned racism of Vic torian England—and as an indicatio that, for all our pressing problems, w have improved somewhat during the pas century:

> Suppose a white man to have been wrecke on an island inhabited by negroes. . . . Su pose him to possess the physical strengt energy, and ability of a dominant white rac . . . grant him every advantage which w can conceive a white to possess over the na tive. . . . Yet from all these admission there does not follow the conclusion tha after a limited or unlimited number of ge erations, the inhabitants of the island wi

white. Our shipwrecked hero would obably become king; he would kill a great any blacks in the struggle for existence; would have a great many wives and chil- en, while many of his subjects would live d die as bachelors. . . . In the first genera- on there will be some dozens of intelligent ung mulattoes, much superior in average telligence to the negroes. We might ex- ct the throne for some generations to be cupied by a more or less yellow king; but n any one believe that the whole island ll gradually acquire a white, or even a yel- w population. . . . for if a very highly fa- red white cannot blanch a nation of ne- oes, it will hardly be contended that a mparatively dull mulatto has a good ance of producing a tawny tribe.

In other words, by blending inheritance, e offspring of the first generation will be ly half white. Most of these, since full acks so greatly predominate (and follow- g prohibitions against incest), will marry ll blacks, and their offspring of the sec- d generation will be one-quarter white. the same argument, the proportion of hite blood will dilute to one-eighth in the ird generation and soon dwindle to obliv- n, despite its putative advantages.

Darwin, or so the story goes, saw the rength of this argument and retreated in ustrated impotence toward the La- arckian views that he had previously re- cted. Whiggery then comes to the res- ue. Inheritance is Mendelian, or "parti- ulate," not blending (though Darwin ed long before the rediscovery of Men- el's laws in 1900). Traits based on genetic utations do not dilute; genes that deter- ine such traits are entities or particles at do not degrade by mixing with genes the other parent in offspring. Indeed, if cessive, a favorable trait will appear in offspring of the first generation (in atings between the favored mutant and dinary partners carrying the dominant ene). But the trait does not dilute to obliv- n. In the second generation, one-quarter the offspring between mixed parents ll carry two doses of the favored reces- ve gene and will express the favored ait. Any subsequent matings between ese double recessives will pass the fa- red trait to all offspring—and it can read through the population if concen- ated by natural selection. (Skin color d height seem to blend because they are termined by such a large number of par- culate genes. The average effect may be blend, but the genes remain intact and bject to selection.)

But this usual story fails when we prop- ly locate Jenkin's point about blending the wider context of an argument that rvades the entire essay—and do not mply extract it as a kernel deserving

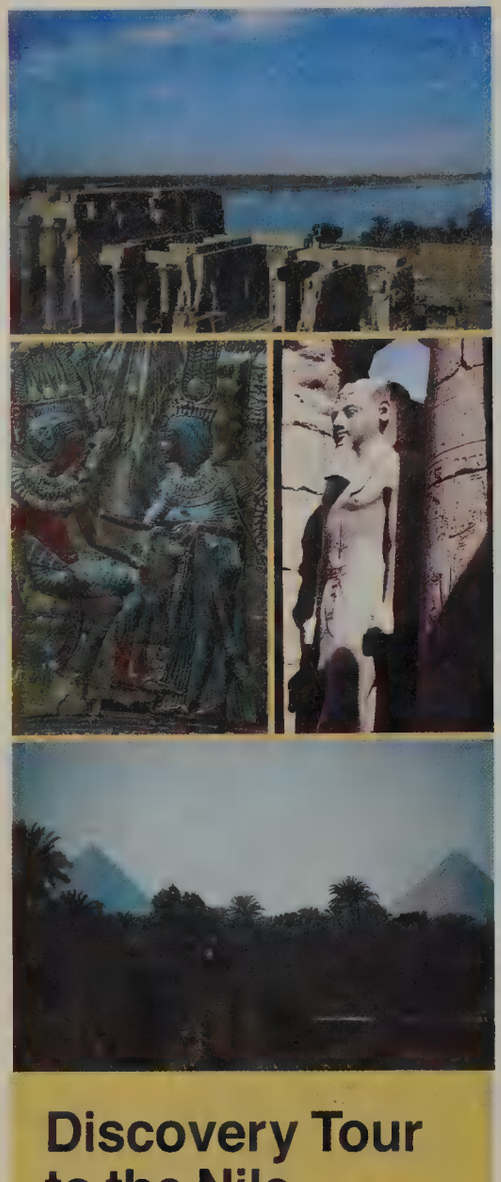
SUN LINE



Discovery Tour to the Nile

February 9 to March 1, 1986

Discover the world of ancient and modern Egypt on an American Museum 600 mile Nile Cruise. Explore with three lecturers the rich natural and archeological sites of an area which has fascinated visitors for centuries...A carefully planned itinerary (with a special two-day program in London visiting the British Museum with its curator) provides a relaxing and thorough three-week Discovery Tour. All of the major Nile archeological sites as well as the important wildlife regions are discussed and visited with your balanced team of eminent lecturers. Share with Museum staff and friends an unforgettable cruise. For further information including itinerary, map, prices, conditions, etc., write or call American Museum Discovery Tours.

modern notice while discarding the rest as chaff. As historian Peter J. Vorzimmer notes in his excellent book, *Charles Darwin: The Years of Controversy* (Temple University Press, 1970), Jenkin presented his arguments about blending in discussing only one particular kind of variation—*single* favorable variants *substantially different* from parental forms.

Darwin was no fool. He had thought about variation as deeply as any man. His longest book, the two-volumed *Variation of Animals and Plants Under Domestication* (1868), summarizes everything he and almost everyone else knew about the subject. Can we seriously believe that he had never thought about problems that blending posed for natural selection, that he needed a prod from an engineer to recognize the difficulty? As Vorzimmer shows, Darwin had pondered long and hard about problems provoked by blending. Jenkin did not introduce Darwin to this basic problem of inheritance; rather, he made a distinction between the kinds of variation that blending affects, and Darwin welcomed the argument because it reinforced and sharpened one of his favorite views. Darwin did not retreat before Jenkin's onslaught, but rather felt more secure in his preferred belief—hence his expressed gratitude to Jenkin and hence (I assume) Stevenson's single comment that Jenkin had convinced "on one point the philosopher himself." Stevenson, the novelist, understood. We have forgotten.

The real issue has been lost in a terminology understood in Darwin's time but no longer familiar. Let us return to Darwin's letter to Wallace, quoting the passage this time in full: "I always thought individual differences more important than single variations, but now I have come to the conclusion that they are of paramount importance, and in this I believe I agree with you. Fleeming Jenkin's arguments have convinced me."

In Darwin's time, "individual differences" referred to recurrent variations of small scale, while "single variations" identified unique changes of large scope and import—and often called "sports." Debate had long focused on whether small-scale and continuous, or occasional and larger, variations supplied the raw material for evolutionary change. Darwin, the quintessential continuationist of this or any other age, had long preferred recurrent small-scale changes but had continued to flirt (largely by weight of tradition) with larger sports. Now, the simple point of Jenkin's argument: Note that he speaks of *one* white man identified (in the racist tradition) as vastly superior to the natives—in other words, a single sport. Jenkin's famous blending argument is only about single, marked variations—not about the continuous recurrent variations that Darwin preferred. By accepting Jenkin's view, Darwin could finally rid himself of a form of variation that he had never favored.

As for recurrent, small-scale variation (individual differences, in Darwin's terminology), blending posed no insurmountable problem, and Darwin had resolved the issue in his own mind long before reading Jenkin. A blending variation can still establish itself in a population under two conditions: first, if the favorable variation continues to arise anew so that any dilution by blending can be balanced by new appearances, thus keeping the trait visible to natural selection; second, if individuals bearing the favored trait can recognize each other and mate preferentially—a process known as assortative mating in evolutionary jargon. Assortative mating can arise for several reasons, including aesthetic preference for mates of one's own appearance and simple isolation of the favored variants from normal individuals. Darwin recognized both recurrent appearance and isolation as the primary reasons for natural selection's continued power in the face of blending.

With this background, we can finally exhume the real point and logic of Jenkin's essay—an issue still very much alive, and discussed (through all his factual errors) in a most interesting and perceptive way by Fleeming Jenkin. Jenkin's essay is a critique of Darwin's continuationist perspective—his distinctive claim, still maintained by the evolutionary orthodoxy—that all large-scale phenomena of evolution may be rendered by accumulating, through vast amounts of time, the tiny changes that we observe in modern populations. I call this conventional view the "extrapolationist" argument; I also share Jenkin's opinion (but for different reasons) that it cannot suffice. I find it supremely ironic that the one small section of Jenkin's article *not* about Darwin's claim for continuity (his argument that single sports will be swamped by blending) has become the only part that we remember—and, to make matters worse, usually misinterpret. Such, however, is the usual fate of Whig heroes and villains (see my previous essays on Steno, Hutton, Cuvier, and Gosse).

A simple, almost pedantic, précis of Jenkin's argument should rescue his larger point. Jenkin's essay proceeds in four parts. The first, on limits of variation, admits that Darwin's favored style of recurrent, continuous variation does occur and can be manipulated by natural selec-

ion to change the average form of a species. But, Jenkin argues, such variations always fiddle in minor ways with parts already present; they cannot construct anything new. Thus, natural selection can make dogs big, small, blocky, or elongated—but it cannot turn a dog into something else. Jenkin expresses this argument in his powerful metaphor of the "sphere of variation." Natural selection may move the average form anywhere within the sphere, but not beyond its fixed limits:

A given animal or plant appears to be contained, as it were, within a sphere of variation; one individual lies near one portion of the surface, another individual, of the same species, near another part of the surface; the average animal at the center.

Common experience, Jenkin affirms, supports his view. Artificial selection practiced by breeders proceeds rapidly at first but soon reaches frustrating limits. Jenkin writes of racehorses:

Hundreds of skillful men are yearly breeding thousands of racers. Wealth and honor await the man who can breed one horse to run one part in five thousand faster than his fellows. As a matter of experience, have our racers improved in speed by one part in a thousand during the last twenty generations?

Darwin, Jenkin claims, maintains an unwarranted faith in the power of simple time to overcome these barriers:

The difference between six years and six myriads, blinding by a confused sense of immensity, leads men to say hastily that if six or sixty years can make a pouter out of a common pigeon, six myriads may change a pigeon to something like a thrush; but this seems no more accurate than to conclude that because we observe that a cannon-ball has traversed a mile in a minute, therefore in an hour it will be sixty miles off, and in the course of ages that it will reach the fixed stars.

Darwin might argue, Jenkin admits, that once a species reaches the limit of its glass sphere, time will eventually reconstitute this edge as a new center and produce a new sphere around the previously peripheral point. Jenkin also rejects this argument:

The average or original race . . . will [in Darwin's view] spontaneously lose the tendency to relapse and acquire a tendency to vary outside the sphere. What is to produce this change. Time simply, apparently. . . This seems rather like the idea that keeping a bar of iron hot or cold for a long time would leave it permanently hot or cold at the end of the period when the heating or cooling agent was withdrawn.

Jenkin's second section, on types of

Anything else is a compromise.

variation, begins by admitting Darwin's point that small-scale recurrent variations will not be destroyed by blending. But these are the very variations subject to strict limits by the previous argument about rigid spheres. What kind of variation might then induce the evolution of something substantially new? Single sports might seem promising, but these are the rare events that will be swamped by blending—and readers may now note where the only bit of Jenkin that we remember lies within his general argument. But perhaps some kinds of sports do not blend but do perpetuate their kind. Fine, Jenkin admits. Perhaps such creatures do occasionally arise and produce new species. But such a process is not Darwinian evolution, for Darwin insisted that natural selection acts as a creative force by gradually accumulating favorable variants. Indeed, would such a process be very different from what the vernacular calls "creation"?

The third part argues that even if Darwin could find (which he can't) some way to accumulate small-scale recurrent variations into something new, geology does not supply enough time for such a slow process. Here Jenkin relied on the false arguments of his dearest friend, Lord Kelvin, about the earth's relatively young age (see my column of October 1983).

The last section presents a powerful (and I think entirely correct) argument about the difficulty of inferring historical pathways from current situations. Jenkin contends that nearly any static situation can arise via several historical routes; thus the situation by itself cannot specify the pathway. Jenkin points out that Darwin bases much of his argument upon the lack of definite boundaries in nature—the intergradation of species into species, or geographic region into region. Darwin's continuationism predicts just such an absence of boundaries since species are gradually and imperceptibly changed into their descendants, while a creator should leave gaps between his incarnated objects. But Jenkin argues that many natural items come as continua, yet clearly do not arise by a process of historical transformation. Arguing, as he always did, by metaphor and analogy, Jenkin writes:

> Legal difficulties furnish another illustration. Does a particular case fall within a particular statute? Is it ruled by this or that precedent? The number of statutes or groups is limited; the number of possible combinations of events almost unlimited.

Taken as an entirety, Jenkin's argument possesses a kind of relentless logic. The critique of Darwin's extrapolationism serves as its unifying theme. Part one argues that small-scale variation cannot extend beyond fixed limits. Part two claims that no style of variation can make something substantially new in a Darwinian world. Part three proposes that even if Darwin could find a way, geology does not permit enough time. Finally, part four holds that we cannot infer historical transformations from the admitted continua of nature.

I don't want to fall into a Whiggish pit and judge Jenkin by current standards (everything that has gone before in this essay adequately discharges, I hope, my dues to anti-Whiggery). But old arguments usually repay our close attention because we often stop discussing the fundamentals once an orthodoxy triumphs, and we need to consult the original debates in order to rediscover the largest issues—perhaps never really resolved but merely swept under the rug of concord. Much of Jenkin's argument fails today, for few things last a century in science. He was clearly wrong about blending in part two and about time in part three. But I believe that he was right about continua in part four and that we are still plagued by our tendency to make an almost automatic inference about history when we fail to find clear boundaries.

The first argument about limits of variation has also risen again in current debates about evolutionary processes. I don't accept Jenkin's metaphor of the sphere because small quantitative changes can accumulate to qualitative effects or leaps (contrary to Jenkin's position), and because I accept Darwin's argument that new spheres can be reconstituted about previously peripheral points.

But neither (probably) is a species the kind of almost equipotential sphere that the strict Darwinians envisaged—unconstrained and capable of rolling anywhere that natural selection pushes. The constraints imposed by genetics and development have emerged as a central topic in contemporary evolutionary debate—and Fleeming Jenkin did present an insight worth considering.

In short, and for many reasons that I can't begin to discuss at this advanced length (but have treated in many previous columns), Darwin's strictly extrapolationist vision may not describe large-scale evolution very well—small, local adaptations built in the refiner's fire of Darwinian competition among organisms struggling for reproductive success may not, by extension, explain trends that persist for millions of years or relays of changing diversity that mass extinctions produce. Jenkin, who presented the most logical dissection of Darwin's continuationist vision in 1867 does reach across a century to set us think ing, however superannuated his specific claims.

We may give the last word to Jenkin via Robert Louis Stevenson. One day as a young man, Stevenson reports, Fleeming Jenkin argued bitterly with two young women about a pressing issue of Victorian hypermorality; can a misdeed agains moral codes ever be condoned, whatever the circumstances—stealing a knife to prevent a murder, for example? (Jenkin to his credit, argued the affirmative.) As he left the house, his anger mellowed. He realized that even the most apparently pe culiar belief deserves respect if argued honorably and if properly constructed upon a set of basic premises different from those usually cherished:

> From such passages-at-arms, many retire mortified and ruffled; but Fleeming had no sooner left the house than he fell into de lighted admiration of the spirit of his adver saries. From that it was but a step to ask himself 'what truth was sticking in thei heads'; for even the falsest form of words (in Fleeming's life-long opinion) reposed upon some truth.

Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.

THE UNICORN.
Fabulous creature of myth whose elusive soul can only be tamed by a maiden's magic power. Reigning favorite with artists for centuries—captured in words by poets—and beloved among collectors as well.

Now, the eternal spirit of this wondrous animal is portrayed as never before—in a remarkable porcelain sculpture embellished with pure gold.

Created by the acclaimed British sculptor David Cornell, "Unicorn, The Messenger of Love" is a triumph of artistry and imagination—a regal interpretation of this mythical horse-like creature. Its body pristine white. Centered on its forehead, a golden horn. Encircling its neck, a golden ruche.

Cornell reveals not only the Unicorn's physical characteristics, but the very essence of its personality—an untamed spirit, graceful as well as powerful . . . sensual as well as mystical.

Each sculpture will be *individually hand-cast and hand-finished.* Each will be crafted in fine European bisque—the porcelain identified with many of the world's most treasured works of sculpture. And, finally, the Unicorn's horn and collar will be *hand-decorated with pure 24 karat gold.* The issue price is $120, payable in convenient monthly installments.

This classic sculpture is available *exclusively* from The Franklin Mint. To acquire "Unicorn, The Messenger of Love"—as an enchanting addition to your home—mail the order form below to The Franklin Mint, Franklin Center, PA by June 30, 1985.

Shown smaller than actual size.
Height: approximately 9 inches.

© 1985 FM

One Potato, Two Potato

Their methods may be scorned, but Newfoundland's gardeners haul in the vegetables

by John T. Omohundro

In recent years, painstaking fieldwork in anthropology has often uncovered a reasonableness, even an ingenuity, in the apparently cloddish methods of the tribal yam gardener or peasant maize farmer. To discover that such farmers were outstanding in their fields, ethnographers have been standing out in the fields with them. And there they clocked the farmers' work time, weighed their harvests, photographed their techniques, and in general submitted their actions to a plethora of measurements designed to assess efficiency and productivity. There is an intelligence, they found, in the customary ways. Food-getting practices, because they immediately affect survival, seem particularly susceptible to a kind of vigorous selection over the years. How we, or the Papua New Guineans, feed ourselves, is not an arena where stupidity could long be tolerated.

No situation better illustrates this notion of peasant wisdom than the lazy beds on the Island of Newfoundland, in eastern Canada. "Lazy beds" is the term commonly used to describe the gardens Newfoundlanders create to grow their winter's supply of potatoes, turnips, onions, and cabbage. The name derives from "lazy root," the English epithet for the potato, which was so common in Ireland and the poor regions of Britain from where Newfoundland's settlers came. The lazy bed results from laying the seed on the surface of the ground and spading soil over it, creating alternating trenches and raised ridges, or beds. The beds are produced with only a few hand tools and tended little between planting and harvesting.

Beginning in the eighteenth century, families left their home districts of Dorset, Waterford, or the Channel Islands to create fishing villages on Newfoundland's coasts. Here were the richest cod schools in the world, but the catch—destined for the world fish market—earned little money with which to buy imported flour, beef, sugar, and tea. For their own consumption, the settlers found it necessary to supplement the local merchants' expensive victuals with hunting, gathering, milking a cow—and gardening, in much the same peculiar manner it had been conducted in the Old World. Unlike the settlers' home districts, however, Newfoundland exists at the very margin of the cultivable world. Compared with Europe, the growing season is a month shorter, and the air colder, windier, foggier, and more likely to deposit frost at any time. The soil is thin and stony and because of its geological immaturity lacks nitrogen, phosphorus, and organic matter. The terrain is usually rough right to the shore. Low rates of evaporation combine with the rains, snows, and mists to leach the soil, making it as acidic as lemonade. The dismaying prospect for crops compelled one survey geologist to wonder in print, "How do you till this land? With a pickax?"

As if the natural conditions were not discouraging enough, there were also cultural and historical obstacles to cultivation. Newfoundland's settlers came from regions where they had been employed tending sheep and cattle or as agricultural laborers. They had kept gardens but were not self-sufficient farmers. Unlike the English countryside, the coasts of Newfoundland had no gentry experimenting and promoting innovations. For centuries, the British government even discouraged cultivation by settlers. Potential mariners for His Majesty's ships, Newfoundland fishermen were kept oriented to the sea. In the settlements, or outports, farming and fishing competed for the family's labor during the peak times of the annual work cycle. Cultivation of the land remained subordinate, even furtive, pursued simply to put food in the larder. It acquired official encouragement or more of the family's attention only when the fishing economy was sacked by world prices or th elusiveness of the cod.

While Newfoundlanders labored unde natural and historical obstacles to raise few vegetables during the summer, the received little praise. Like its Europea ancestor, the Newfoundland lazy bed ga den acquired critics like weeds, each com peting for the most memorable insult t these peasant practices. The primitiv lazy beds, with their folk origins in earl Celtic farms and their association with ig norant poverty, were the compilation o every procedure incompatible with mech anized farming. And the anathema unde which European lazy beds were place followed Newfoundland settlers to th New World. Since the nineteenth centur both provincial and foreign experts hav attacked the lazy beds, their manurin the hand tools, and the labor involved—o lack of it. Most writers, being advocates o progress and modern agriculture, hav concluded that the isolated, illiterat Newfoundland outporters, with their a tention turned to the sea, were abysma truck farmers. For example, the nine teenth-century tourist and author Cap R.B. McRae fumed, "Heaps upon heap of caplin [a small fish] are spread broad cast over the fields for manure, a practic as stupid as it is shortsighted." He contin ued, apocalyptically,

> Nature, careful of her gifts and riche never intended the harvest of life to be use to so vile and wasteful a purpose, withou first undergoing preparations by other nec essary transitions. The farmer, by using fis as a manure, enriches his pastures for a sea son, but impoverishes the ground rapidl while, in revenge for the outrage, vast myr ads of insects, grubs, and caterpillars ar developed from the putrid soil, suddenl overenriched, and which soon spread havo wholesale in fields and gardens on ever side.

Less colorfully, twentieth-century wri

The Metropolitan Museum of Art & The National Gallery of Art

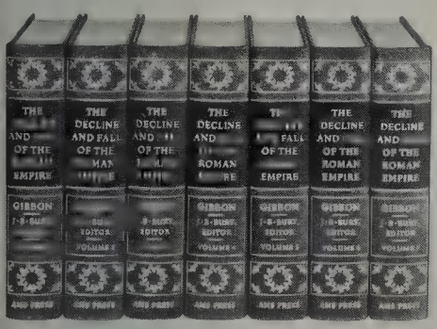
for **$17.95** (Pub. prices total $110)

The Metropolitan Museum of Art surveys the Met's entire collection, with more than 1050 plates (602 in full color). *The National Gallery of Art* reproduces the gallery's greatest treasures with 1120 illustrations, including 1028 plates in full color, many printed with gold.

The Compact Edition of The Oxford English Dictionary

for **$24.95** (Pub. price $175)

"The most complete, most scholarly dictionary of the English language"—*The Christian Science Monitor.* Through photoreduction, the original 13-volume set has been reproduced in this two-volume *Compact Edition.* A Bausch & Lomb magnifying glass is included.



The Decline and Fall of the Roman Empire by Edward Gibbon. Edited by J. B. Bury

for **$24.95** (Pub. prices total $300)

The definitive Bury edition of the most acclaimed history of all. Gibbon evokes a world of grandeur and decadence, masterfully tracing its collapse under emperors noble and ignoble. Seven-volume set, newly available with maps and illustrations on long-lasting acid-free paper, quarter-bound in genuine leather.

The Story of Civilization by Will and Ariel Durant

for **$29.95** (Pub. prices total $335.45)

For almost half a century Will and Ariel Durant traced the continuity of world history—the religions and philosophies, the political and economic tides, the arts and sciences, the customs and conquests—to show the foundations of society today. A Book-of-the-Month Club exclusive for almost 50 years, the Durants' illustrated masterwork is history come alive.

Facts About Membership. As a member you will receive the *Book-of-the-Month Club News*® 15 times a year (about every 3½ weeks). Every issue reviews a Selection and more than 125 other books that we call Alternates, which are carefully chosen by our editors. If you want the Selection, do nothing. It will be shipped to you automatically. If you want one or more Alternates—or no book at all—indicate your decision on the Reply Form and return it by the specified date. *Return Privilege*: If the *News* is delayed and you receive the Selection without having had 10 days to notify us, you may return it for credit at our expense. *Cancellations*: Membership may be discontinued, either by you or by the Club, at any time after you have bought four additional books. ers persist in a nearly blanket condemnation. A geographer has written, "Lack of crop rotation, with little fertilizer added save a part of the annual caplin haul, has caused the depletion of fertility instead of the replenishment that might be expected." Even an agricultural specialist and native of the province claimed in exasperated tones, "I'm against lazy beds. It is too much work, it doesn't allow for cultivation, and the nutrients leach out of the beds into the ditches. You can see this in abandoned potato gardens—the ditches have richer vegetation than the beds!" Perhaps inevitably, anthropologists have also picked up this bias. Writing of gardens in Cat Harbour, on the northeast coast, James Faris maintained that deep-water kelp and caplin fertilizers actually depleted the soil.

This, then, is a test for the ecologically minded anthropologist: Can the gardening be that wretched? Are lazy beds a bad Newfie joke? Definitely not. As my wife, Susan, and I discovered on our field trips to Newfoundland, the marginal environmental conditions make gardens risky and the fishing economy makes them merely a sideline occupation, but a gardening tradition has evolved that assures a reliable source of food as well as some critically short nutrients. Lazy bed gardening economizes on labor, cash, and time; it exploits local resources and tools; it improves growing conditions; and it reduces the risk of garden failure presented by unpredictable weather or pests.

An average outport family of four may have a garden of twenty beds, each three by thirty feet and containing about one hundred seeds. To make a bed, kelp is spread over the ground, the seeds are placed on it, and the whole is layered over with soil spaded up from one-foot-wide trenches dug around the bed. The resultant bed is six to ten inches higher than the original land surface, and the trenches are about six inches deep.

Compared to conventional gardening methods, prevalent elsewhere in North America, lazy beds require little of a Newfoundland family's precious summer labor. Planting densely—one plant per square foot—means that there is less work hauling and spreading fertilizer over large areas. The beds can be prepared with only a triangular "trenching spade" and a rake or pitchfork. Their compactness minimizes the building and maintenance of fences. Weeding is reduced—the full green canopy the dense vegetables create by July shuts out the weeds. And because gardeners limit their movements to the trenches around each bed, the ground remains loose.

The lazy beds also compensate for natural hazards. The raised bed protects young plant roots from waterlogging during the overly wet spring. Should the summe turn very dry, as it can in July, gardener may block off trenches to hold water an cover the beds with any available gree rubbish to reduce evaporation. Researc also shows that lazy beds can be warme than the surrounding land. Morning tem peratures on a raised bed, for example can be eight to ten degrees higher. Seed i planted just below the surface of the soil and earlier in the spring than would b possible in a ground-level garden. Thi capitalizes on the sunshine of the lon June days, which encourages early sprout ing—an important advantage where th growing season is so short. In addition beds are often deliberately built on slopin ground, where drainage is improved Slopes that face south receive stronge sunlight, creating a microenvironmen with conditions equal to those found man miles farther south.

Spading soil from the trenches severa times during the growing season return leached nutrients to the beds. Beds an trenches are often alternated annually Newfoundlanders have been criticized fo depleting the soil by intensively plantin the same plot year after year. But how ca a soil be depleted that has so little to begi with? What fertility a garden possesses i put there by the gardener. "Making soil" is the family's annual chore. Formerly rotted stable manure was hauled into th

Olympus invents ESP for cameras.

Without ESP

With ESP

And suddenly the mind and the camera are one.

Because the new Olympus OM-PC has been blessed with ESP (Electro Selective Pattern metering).

So now you can skip that awkward stage known as beginner.

ESP is a mini-computer brain that intuitively knows what the eye is seeing, and automatically adjusts for light intensity and contrast. All the way from backlit to overlit.

And after you find the exact image you want in the viewfinder, Off-the-Film metering (OTF.™) lifts it out of the air on to film the instant you see it. Just as you see it.

Since the OM-PC also features a choice of Program, Automatic, or Manual modes and prevents all common lighting mistakes, it advances the beginner automatically. While offering the option of over 300 compatible OM System accessories.

You'll see the true value of ESP when you pick up your first set of photos. And discover rich, natural colors instead of washed out or murky prints.

Of course, if you were born with ESP, this whole ad was unnecessary.

You already know the OM-PC will be your first Olympus SLR.

OLYMPUS

There is no longer a choice.

Now, after the new OM-PC. Write Olympus, Dept. 21, Woodbury, NY 11797, or call 1-800-622-6372 (in Canada, call Olympus Canada Inc., 90 Tycos Dr., Toronto, Ont. M6B 1W3, 789-2600).

garden at winter's end by dog teams or by children with hand barrows. Today, as well as in the past, kelp and rockweed—accumulated in piles on the beach after winter and ice storms—are forked onto the beds up to a depth of six inches.

The seaweed contains colloids that help sweeten the soil. It also replaces potassium and nitrogen that the spring rains leach from the surface. The decay of the kelp takes up nitrogen, which is scarce in the spring, but releases it again during dissolution. Biological research also suggests that rockweed contains a growth hormone and a substance to increase the plant's resistance to frost—likely to occur in the early weeks of emergence. Banked around cabbage stems, the rotting kelp may also confuse the destructive root maggot fly, which chooses where to lay her eggs by smell. (Some gardeners also apply tobacco juice, paprika, or other remedies to discourage the fly.) Finally, the salt in the marine manures actually aids a salt-deficient bog mud, facilitating the nutrient uptake of the plant roots.

"Set 'em in kelp, trench 'em in caplin," the gardeners say. Like kelp, the small silvery caplin fish are a clever garden supplement. By mid-June, when these fish run in the millions onto the shores, outporters scoop net barrelfuls to blanket their gardens. Caplin add calcium and phosphorus to sweeten the soil and to balance the kelp's contribution of potassium. As the whole fish carcass decays, it slowly releases nutrients into the rapidly leached soil. Used in this way, caplin are "time-release capsules," feeding plants when gardeners are busy at other tasks. In some areas, gardens are planted right in the beach sand, so most fertilizer washes up within pitching distance.

But ingenious fertilization techniques are not sufficient to assure a good harvest. Newfoundlanders are compelled by poor soil to cultivate their land intensively. Gardeners bludgeon a crop from a piece of ground. They plant three times as much seed per unit of land as do commercial Newfoundland potato farmers, heaping on three times as much manure and fertilizer. Although their return per pound of seed averages only half of what the commercial farmer gets (6.5 to 15.0 pounds per pound of seed, compared to 17.1 to 28.6 pounds), gardeners usually come out ahead in the yield per acre. For example, in 1982 (not a particularly good year), the thirty gardeners we observed hauled 78 percent more potatoes per acre than the Newfoundland commercial farmers. The comparative loss in efficiency of seed and fertilizer invested in their gardens is more than compensated for by the likelihood of a sufficient crop. A good year means potatoes twice a day for months, plus some to give away or sell. And a bad year will still yield about ten pounds of potatoes per capita per month, from October until June.

In the end, the lazy bed garden costs the outporters little for their vegetables, and it saves them much. An average garden consumes about eight person-days of labor—labor that has little cash value because the time is plucked from the gaps in the day's major chores of fishing or wagework. During the idle days of early spring, for example, the dwindling supply of potatoes for seed is eked out by cutting them into egg-size pieces, each with a sprouted eye. Commercial farmers do not do this, both because of the labor and the risk of plant disease. Individual garden work is lightened because the labor is shared by groups of workers—families or extended families—who entertain themselves while they work.

Until the 1950s, no cash was spent in gardening, but then, little cash was available. Nowadays, fertilizer or seed may be purchased at a cost of $46–$78 per gar-

you're likely to see in your region

CHOOSE AMONG THE 7 NEW

AUDUBON SOCIETY NATURE GUIDES

We take pleasure in announcing a splendid new development in field guides.

Until now, if you wanted to go on a nature walk—not just in search of birds, for example, but curious about everything you see—you'd have to take along a whole knapsack-full of field guides: one for wildflowers, one for butterflies, one for trees, etc., etc.

No longer necessary! Now, with the *Audubon Society Nature Guides*, one field guide will do the trick.

This is how the guides work

■ Each covers one region (one type of habitat) and enables you to identify the many kinds of flora and fauna you're likely to see.

For example: If you're at a beach resort on Long Island or in Massachusetts or Florida or anywhere along the eastern shore, you take along the guide called *Atlantic & Gulf Coasts*, which describes—and individually illustrates in color—more than 600 seashells, seashore creatures, fishes, reptiles, amphibians, insects, plants, types of seaweed, birds, and mammals.

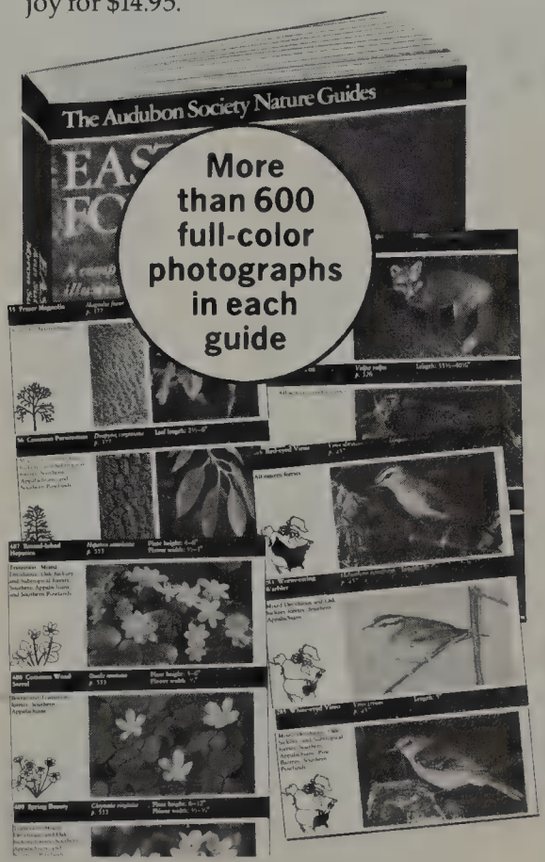
In addition, a comprehensive essay explores the natural history of this region's rocky shores, beaches, dunes, estuaries and bays, salt marshes, coral reefs, and mangrove shores. Pictures and text are indexed and cross-referenced. Everything is here to make the guide easy to use.

■ Each guide contains more than 600 identification photographs in brilliant full color, plus many maps and black-and-white drawings.

■ Each has precise information about the individual species pictured as well as more than 50,000 words of informative text about the particular habitat covered.

■ Each is eminently portable—with 600 to 680 pages (5½″ x 8⅝″).

■ And each guide—authoritative, beautiful, and fun to use—is a bargain and a joy for $14.95.



Don't go outdoors without one!

With a new *Audubon Society Nature Guide* in hand, the ordinary nature walk can become a special adventure. Beginners can discover the variety of living things that co-exist in any habitat. Seasoned nature lovers will derive new insights and find their days outdoors enhanced.

The seven guides

den—less than one and one-half days' wages at a local fish plant. The return of more than thirteen pounds of potatoes per dollar invested compares favorably with the commercial farmer's return of fifteen pounds per dollar (not counting the capital investment involved in mechanized farming). The average garden's yield would cost from $100 to $200 in the shops in the fall; stored in semi-subterranean root cellars, the crop more than doubles in value by spring, if the merchant's vegetable prices are taken as a guide. Newfoundland's lazy beds are thus a balanced investment of land, labor, time, and materials, in which people exploit limited resources to overcome prodigious obstacles.

How did the Newfoundlanders arrive at this system? Do the gardeners understand the value of what they're doing and why it works? Probably no individual is aware of the whole picture, and most of the gardeners cling to a few oddball notions, such as the belief that lightning wilts potato vines. But collectively, a community of gardeners knows most of what is reported here. And because gardening is both competitive (it confers prestige to cultivate a bountiful garden) and highly sociable (people trade labor and seed and endless talk about gardens), the collective wisdo is constantly redistributed. The mech nism for the evolution of Newfoundlar gardening from its European origins is th accumulation and success of small exper ments, serendipitous discoveries, and in perfect imitations over the three hundre years of settlement.

Never widely acknowledged, lazy be gardening was nearly forgotten whe Newfoundland joined Canada in 194 Unemployment compensation, retiremer benefits, and welfare checks became si nificant parts of family income. The fis ing and logging industries were revitalize for a time, and they paid well. Roads b gan to connect isolated communities regular groceries, to commuting wag work, health care, and other convenienc of civilization. Some isolated communitie were simply evacuated. Hoping to catc up with twentieth-century Canada, New foundlanders consequently abandone home food production. "Gardens, goat and berry picking" were stigmatized a remnants of the depression years. Canne goods, and houses modeled after those Toronto suburbs, became fashionabl Pasture fences fell into disrepair, an eight-foot-high weed forests replaced th trim rows of potato and cabbage plants

By 1965, household food productio had fallen to an all-time low, with less tha half the community growing anythin Gardens were small and contained fewe crops. Bad years "at the fish" or "in th woods," rather than prompting a retreat self-sufficiency, encouraged a mass ex dus of young men and women to the fa tories, forests, and oil fields of mainlan Canada. The outports lost many appre tice gardeners and strong workers. Th survival traditions appeared to be dyin with the older generation.

But by the 1970s, outport residents rea ized that rapid progress toward the grea Canadian mean would be much slowe than anticipated, if it occurred at all. In flation had skyrocketed, and workers lai off in Toronto and Alberta returned t their families. Only ten years after oil an electricity had made hot-air furnaces stan dard, they were being replaced with al night woodburners. "Worst we ever done give up the cows, the gardens," one ga dener told us. "We gave 'em up becaus we thought times was getting better. Bu they weren't. People are going to have t go back to the ground again."

As Newfoundlanders moderated thei expectations, gardening's decline levele off in the 1970s and even made a slight re covery. On the island's Great Norther Peninsula, where we have concentrate our fieldwork, about half the families ar

now spading a garden in May. Familie are smaller, tastes have changed, and s gardens are accordingly smaller and mor experimental. A gardener's prestige sti depends upon the quality and quantity o the potatoes, but extra merit is earned no from lettuce, strawberries, or onions. In spired by mainland seed catalogs, the opt mist nurtures—and invariably loses—a tomato or a pumpkin.

Today, the revived gardening traditio continues to evolve, sometimes aided b government funds. Two innovations in re cent years are greenhouses and communa gardens. The opening of the highway ont the peninsula in the 1960s increased th ease of reaching plots distant from the ou ports. Since the improvement of the road involved a great deal of earth moving an the opening of gravel pits, the use of so turned up along the highway is extensive Gravel pits, easily tilled and functionin as solar collectors, have become popula garden locations. And the roadside bank of drained peat or sandy soil, often slante to the sun, are easily accessible. Such roadside gardens were widespread i Devon and Dorset, but the Newfoundlan practice appears to be an independent in vention under similar economic and geo graphic circumstances.

Knowledge of Newfoundlanders' ga dening techniques could be of practica benefit to readers who garden in similar cool, wet, and infertile regions. Settler once raised vegetables in lazy bed garden in the Adirondack Mountains, on Sain Lawrence River islands, and on the rock coast of Maine. But commercial food be came available year-round in those area many years ago, and the tradition dwin dled before it was fully recorded and ap preciated. In Newfoundland, by contras the centuries-old gardening tradition ha been preserved because until recentl commercial foods were scarce and expen sive. Outport gardens are anachronism but instructive ones. The example the provide expands our agricultural option increasing our flexibility today to fee ourselves in a wide variety of enviro ments. If nothing else, the realization tha Newfoundland lazy beds are clever in stead of ridiculous should give pause t those whose world view is stamped on with the image of commercial energ intensive agriculture.

John T. Omohundro is an associate pro fessor of anthropology at the State Un versity College of Arts and Sciences Potsdam, New York. Since 1979, he an his wife, Susan, have visited the Island Newfoundland each year to preserve th local lore about subsistence activities.

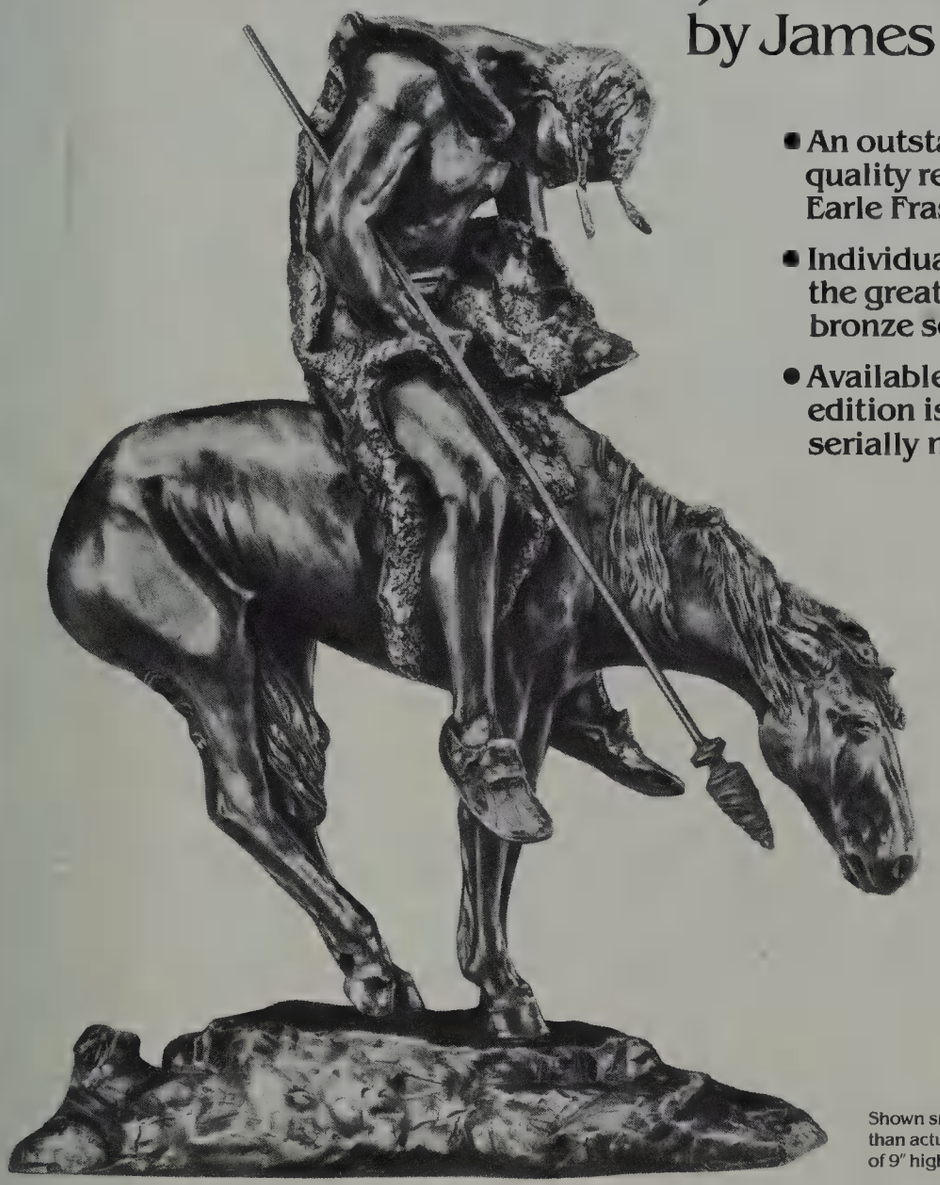
"The End of the Trail"

by James Earle Fraser



- An outstanding museum quality reproduction of James Earle Fraser's greatest work.
- Individually hand-finished in the great tradition of classic bronze sculpture.
- Available in a single limited edition issue of just 9500 serially numbered sculptures.

Shown smaller than actual size of 9" high.

One of the most beloved and acclaimed sculptures in American history, "The End of the Trail" is James Earle Fraser's world renowned tribute to the American Indian. The few existing bronze originals are virtually beyond valuation, but now this magnificent ⅓ size museum quality reproduction is available for the exceptional offering price of just $195.00 per sculpture.

This extraordinarily detailed and faithful reproduction has been created under the direct supervision of Ms. Christine Roussel — former Director of the Reproduction Studio of the Metropolitan Museum of Art.

Each "End of the Trail" sculpture will be meticulously crafted of cold-cast bronze — a remarkable medium that holds even finer and more intricate detail than traditional hot-cast bronze. Every sculpture will be individually cast from a special blend of powdered resins and bronze, then hand-finished with a classic patina, similar to the original. Each "End of the Trail" will be hallmarked and serially numbered. A Certificate of Authenticity will accompany each sculpture.

The edition will be strictly limited to just 9500 pieces worldwide and after that, all molds will be destroyed forever. To reserve this important Limited Edition Fraser reproduction, simply return the reservation application below. No payment need accompany your order at this time.

Croatan National Forest, North Carolina

by Robert H. Mohlenbrock

On casual inspection, Croatan National Forest is unalluring. This small pineland on North Carolina's coastal plain contains large expanses of boglike habitat with scrubby vegetation. But in these areas, where the soil is generally too poor to support trees, grows the widest selection of carnivorous plants found in any U.S. national forest.

The alternate life style of carnivorous plants arouses almost everyone's curiosity. It is not true, as botanist G.E. Rumphius reported from Malaysia in 1783 (and as *American Weekly* magazine told its readers in the 1920s), that there are vicious plants in Madagascar, the Malay Archipelago, and the Philippines capable of killing and even swallowing humans. But there are some 350 different kinds of flowering plants in the world that trap and digest insects and other small animals. Since their victims include small amphibians and reptiles and an assortment of invertebrates, they are referred to as carnivorous, rather than insectivorous, plants.

Botanists recognize forty-five species of carnivorous plants in the United States, and at least eleven of these live in Croatan. The Venus's flytrap is the most famous, probably because the movements of its inch-long traps are easily observed. The plants' traps are twin-lobed leaves that are hinged between the lobes. Each lobe is rimmed with narrow, stiff teeth and bears three slender, supersensitive hairs on its inner surface. If two of these hairs are touched within a period of about thirty seconds, the two lobes of the trap close, and the teeth along their edges become intermeshed.

The requirement that two hairs need to be touched to trigger the trap is a way the plant saves energy. If an inanimate, and therefore probably nonnutritious, object brushes a hair by chance, the trap remains open. But an insect crawling on the trap is apt to brush against two of the hairs sooner or later, triggering the trap. At first, the teeth along the edges do not intermesh completely, allowing very tiny insects, which have little food value, to escape. If there is no substantial prey, the trap then reopens, but if the insect is large and continues to wriggle, the trap closes completely. Once entombed, the insect is digested in twenty-four to thirty-six hours by enzymes. Afterwards, the trap reopens and lies in readiness for its next meal.

Venus's flytrap and other carnivorous plants possess chlorophyll and thus are capable of manufacturing their own nutrients; their carnivory is an adaptation to nutrient-poor environments. In Croatan National Forest, the habitat in which they grow is known as pocosin, from an Algonquian expression that means "swamp on a hill." Pocosins are flat, slightly elevated areas with poor drainage, ranging up to several hundred acres in extent. They seldom flood, but small pools may appear during the winter.

The pocosin's ooze of black soil looks rich but is highly acidic. Soil acids combine with bases to create water-soluble salts; in this form, many essential soil minerals are washed away by the frequent drenching rains. The soil gets its deceptively rich appearance from carbon—charcoal left by spring fires. Spring is a dry season in Croatan, and plant debris from the previous growing season dries out rapidly. Fires commonly break out and remove the litter, inhibiting the growth of shrubs and aiding the carnivorous plants, which thrive in sunlight. When natural fires fail to suppress shrubs, U.S. Forest Service personnel sometimes supervise controlled burning.

In addition to the Venus's flytrap, ten other species of carnivorous plants are

Edward Schell

found in the Croatan pocosins: two pitcher plants, two sundews, a butterwort, and five bladderworts. A pitcher plant has one or more tubular or funnel-shaped leaves with an opening at the upper end known as the mouth. Projecting upward beyond the mouth is a lid, or hood. Early naturalists, including Linnaeus, thought that the lid was hinged and could be opened or closed by the plant to regulate the amount of water that accumulated inside the pitcher. Actually, the position of the lid is fixed. The eighteenth-century naturalist Mark Catesby speculated that the pitchers were used as hiding places for frogs and other small animals. It wasn't until 1817 that a physician, Dr. James Macbride, realized that the pitchers were able to attract flies with a sweet secretion. He noted that once it has fallen into the bottom of a pitcher, a fly cannot escape because downward-pointing hairs line the leaf's inner walls.

Like flowers, most pitchers are brightly colored to attract nectar-seeking insects. The thick rim, which secretes nectar, is colorful, shiny—and slippery. The visiting insect eventually slips on the rim surface and falls into the bottom of the pitcher, which contains a mixture of rainwater and digestive enzymes. A pile of undigested insect skeletons eventually accumulates within the plant.

Two of the 120 kinds of sundews in the world live in very damp areas in Croatan. Sundews are perky-looking little plants whose crowded rosettes of leaves form at ground level. All the leaves secrete droplets of a colorless, sticky liquid at the tips of countless slender hairs. Insects that venture on them are unable to pull free and eventually perish. Sundew leaves also have enzyme-producing glands, mostly along the center of each leaf, and an insect caught in this area is engulfed quickly. Should an insect land near the edge of the leaf, the hairs will bend inward, transporting the captive to where the enzymes are concentrated.

The blue butterwort, or *Pinguicula*, is another kind of "flypaper" plant. Although it is not related to the sundews, the butterwort also has all its leaves in a basal cluster. A sticky substance covers the upper surface of these leaves, but not the tips of hairs, as in the sundews. If an insect gets mired down on one of the gummy leaves, the leaf curls slightly so that the surface becomes concave, forming a basin in which the digestive enzymes accumulate.

Numerous depressions with shallow standing water dot Croatan, and most of them support still another group of carnivorous plants, known as bladderworts. Five kinds of bladderworts grow in or along the margins of these depressions, their intricately branched stems floating in the water. All along the stems are transparent, air-filled bladders about one-sixth of an inch long. Each bladder has a small mouth at one end, but the mouth is normally closed by a trap door. When a tiny water animal swims into contact with one of two trigger hairs at the entrance to the mouth, the trap door suddenly swings inward, and the inrushing water sweeps the animal inside. The water filling the bladder forces the trap door closed, and the prey is condemned to digestion by enzymes secreted within the chamber. After several hours, the water is forced out of the bladder, and the trap is set again.

Charles Darwin, one of the first scientists to consider the biology of carnivorous plants, was aware that pitcher plants, sundews, and others of their kind were adapted to poor soils. But what nutrients are missing from lands like the pocosins? Because plant growth is often inhibited by lack of assimilable nitrogen, scientists had long assumed that plants developed carnivory specifically to supplement their nitrogen sources. However, botanists Lionel Eleuterius and S.B. Jones, Jr., working with carnivorous plants in Mississippi, found that the soils that supported these plants were not deficient in nitrogen, phosphorus, or potassium. When fertilizers that contained these elements were applied to the soil, the carnivorous plants actually did poorly. Recently, zoologist George Folkerts suggested that a shortage of trace elements—particularly molybdenum, which is scarce in acidic soils—may have been the key to the development of carnivorous plants. The Fish and Wildlife Service has been studying pocosins for their value as a wetland resource. The results of their soil analyses may shed further light on the relationship between carnivorous plants and their characteristic habitat.

"This Land" highlights the biological phenomena of the 153 U.S. national forests. Robert H. Mohlenbrock is professor of botany at Southern Illinois University at Carbondale.

A young frog falls victim to Venus's flytrap.

On taking leave of Germany... and his teammates.

His tour of duty was over. This was his final good-bye. He remembered all the good times, the joking and that special closeness that comes from sharing not only victory, but defeat.

As he shook hands with Willi, Rolf, Dieter and the others, he realized they had become brothers.

And that was something he'd never forget.

Call West Germany. Ten minutes can average just 81¢ a minute.*

Saying good-bye is never easy—but saying hello is, with AT&T. A ten-minute phone call to West Germany on AT&T can average as little as 81¢ a minute.

Just dial the call yourself any night from 6 pm until 7 am.

If you don't have International Dialing in your area, you'll still get the same low rate as long as special operator assistance is not required.

Germany		
Rate Level	**Average Cost Per Minute For a 10-Minute Call****	**Hours**
Economy	**.81**	6pm–7am
Discount	$1.02	1pm–6pm
Standard	$1.35	7am–1pm

Average cost per minute varies depending on length of call. First minute costs more; additional minutes cost less. All rates are for calls direct from continental U.S. during hours listed. Add 3% Federal Excise Tax. For further information, call our International Information Service, toll free: **1 800 874-4000. *During Economy time periods.

Marine pondweeds are flowering plants that are usually submerged. When they bloom, their pollen is carried not by the birds or the bees but by water.

Noodles on the Tide

Why is water-borne pollen so long and stringy?

by Paul Alan Cox

In 1827, Scottish botanist Robert Brown placed some pollen grains in water for study under his microscope. His initial excitement upon finding the particles "very evidently in motion" was soon dampened when subsequent control experiments revealed that small particles of wood, metal, and stone moved just as actively under the same conditions. Brown, to his disappointment, had not discovered the essential force animating all life but had demonstrated that all small particles, regardless of their composition, exhibit random motion in water.

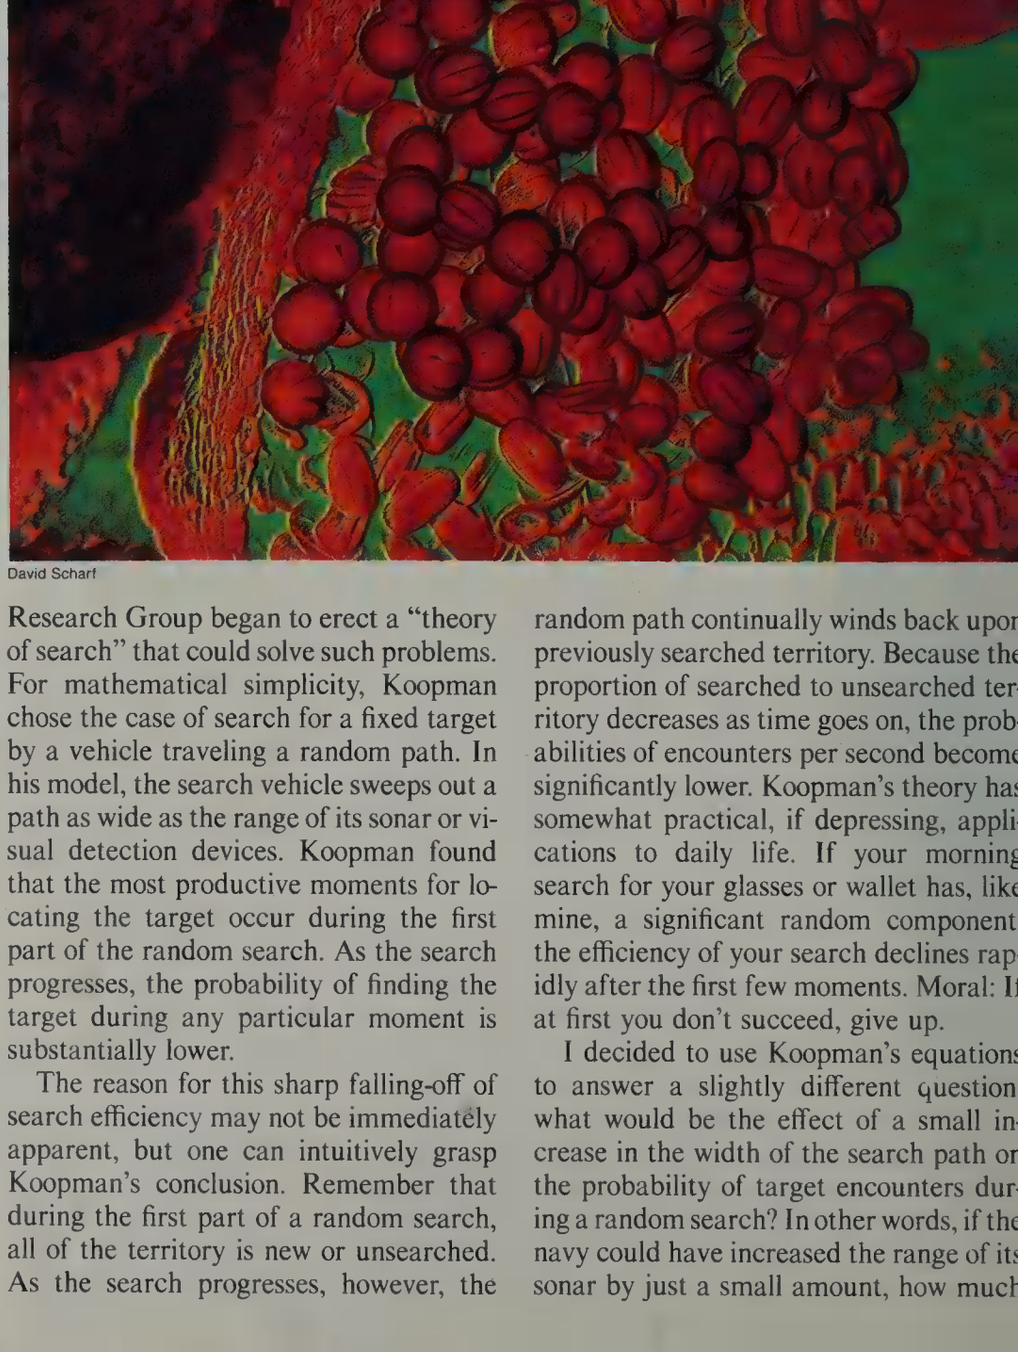
The observations were published as a minor curiosity and largely ignored until the concept they embodied was resurrected by modern physics. Einstein's mathematical exploration of the forces observed by Brown led to the acceptance of the idea that atoms and molecules were real entities, not just theoretical concepts useful in explaining the physical world. Later, Jean Perrin used Brownian motion to obtain a value for the Avogadro number, a feat for which he was awarded the Nobel Prize in 1929.

While botany has not become the main beneficiary of botanist Brown's experiments with pollen, the mathematics of random motion inspired by his observations now provides insights into the system that originally attracted his attention—the movement of pollen grains and fungal spores in water. Among other things, his insight has helped explain why some aquatic flowering plants have such large pollen grains and why aquatic fungi have such large spores.

In most aquatic flowering plants—such as watercress and lotus—pollination takes place the same way it does on land. Wind or insects, birds or animals, carry pollen from flower to flower. In some species, however, pollen is carried on or in the water. Within this group, the sizes and shapes of pollen grains are strikingly similar. They are either very long and threadlike or packaged in elongated conveyances. And compared to land plant pollen grains, which are so tiny that they cannot be seen without a microscope, water-borne pollen is huge.

A typical example is *Thalassadendron,*

Garry T. Cole



David Scharf

a sea grass that grows along the coasts of the Red Sea, the western Indian Ocean, and Australia. Its pollen grains are nearly one-quarter of an inch long—more than 120 times the size of land pollen—and look for all the world like thin spaghetti noodles floating in the tide. Pollen grains of the Australian sea nymph, *Amphibolis*, are not only long and slender but also have hooked ends, which catch on to one another and form ropelike chains that float through the water.

Perhaps even more unusual is the pollen of *Halophila* (the sea wrack), a small sea grass common in shallow water off the coasts of many islands in the South Pacific. In Samoa, a diver with a mask and snorkel can easily observe sea wrack plants well inside the reef at wading depth. Long lines of evenly spaced small plants with oval-shaped leaves seem to emerge directly from the sandy bottom. A tug on a portion of this line reveals, however, that what appears to be a group of separate plants is in fact one plant, connected by hidden horizontal runners called rhizomes. A single genetic individual can occupy several hundred linear feet of the white surface sand.

The sea wrack rarely blooms, but when it does, the male plants produce pollen that is packaged and dispersed in a remarkable fashion. Most flowers produce pollen grains in groups of four, called tetrads. As they mature, the tetrads divide into four separate grains, which are then individually dispersed. Sea wrack pollen grains, however, remain fused in tetrads, and these clusters are dispersed within a very long mucilaginous tube that floats through the water.

Is there a functional explanation for such odd pollen forms or do they merely represent interesting but insignificant quirks of nature? I began to suspect that there was an adaptive explanation for the structure of sea grass pollens when, during the course of another study, I stumbled upon a series of papers on antisubmarine warfare. During World War II, the U.S. Navy asked Bernard Koopman, a mathematician at Columbia University, to help devise ways to locate Nazi U-boats. Koopman and his colleagues in the Operations Research Group began to erect a "theory of search" that could solve such problems. For mathematical simplicity, Koopman chose the case of search for a fixed target by a vehicle traveling a random path. In his model, the search vehicle sweeps out a path as wide as the range of its sonar or visual detection devices. Koopman found that the most productive moments for locating the target occur during the first part of the random search. As the search progresses, the probability of finding the target during any particular moment is substantially lower.

The reason for this sharp falling-off of search efficiency may not be immediately apparent, but one can intuitively grasp Koopman's conclusion. Remember that during the first part of a random search, all of the territory is new or unsearched. As the search progresses, however, the random path continually winds back upon previously searched territory. Because the proportion of searched to unsearched territory decreases as time goes on, the probabilities of encounters per second become significantly lower. Koopman's theory has somewhat practical, if depressing, applications to daily life. If your morning search for your glasses or wallet has, like mine, a significant random component, the efficiency of your search declines rapidly after the first few moments. Moral: If at first you don't succeed, give up.

I decided to use Koopman's equations to answer a slightly different question: what would be the effect of a small increase in the width of the search path on the probability of target encounters during a random search? In other words, if the navy could have increased the range of its sonar by just a small amount, how much

Flowering plants that bloom on land produce pollen that is spherical and microscopically small (facing page, bottom). Water-borne pollen, however, is often long and threadlike (this page, right) and large enough to be visible to the naked eye. Similarly, fungi that grow in water commonly produce large and fantastically shaped spores (facing page, top, and this page, left). Mathematical analysis predicts that large size and complex shape increase search efficiency.

C.A. McConchie

would it have increased the chances of locating a stationary target in a random search? To my surprise, even a small increase in the width of the path results in a vast increase in the likelihood of encountering a target. The biological implications of this observation are intriguing. Anything that increases the average width of the path swept by an aquatic pollen grain should greatly increase the probability that it will hit its "target"—the female stigma of a plant—during a random search. On the basis of search efficiencies alone, elongated shapes or large search vehicles should help aquatic pollen grains find the stigma.

Imagine, for example, the width of the path swept by the search vehicles of water nymph (*Najas*) pollen. In these freshwater plants, the pollen is small and round but has the unusual habit of germinating before it leaves the anther. (When a pollen grain germinates, it grows a pollen tube, the structure through which a nucleus will pass to fertilize an egg. Most pollen grains, terrestrial or aquatic, germinate *after* contact with a stigma.) Thus the water nymph's pollen grain with its long tube becomes the male search vehicle, sweeping an average path equal in width to the pollen grain diameter plus the length of its pollen tube. Early pollen tube formation also occurs in the marine turtlegrass *Thalassia* and in the water starwort *Callitriche*, found in shallow ponds in California. Similarly wide search paths are also obtained by the flowering hornwort *Ceratophyllum*, which releases entire pollen-bearing anthers equipped with floats that carry them from underwater to the surface. The anthers are about thirty-three times larger than the average diameter of airborne pollen.

Perhaps the most startling and beautiful means of improving search efficiency occur in the freshwater eel grass *Vallisneria* and in the unrelated marine flatweed *Enhalus*. Found in quiet freshwater ponds and streams throughout the world, eel grass is also popular as an aquarium plant. It grows submerged and has long, straplike leaves up to six feet long, depending on the water depth. The leaves are produced from a central tuft anchored in the pond mud, and the plant spreads by runners.

Flatweed grows in shallow water off the coast of Australia and various islands in the South Pacific. The plants have long, belt-shaped green leaves up to about two feet long. During flowering, the water surface above the plants seems littered with white confetti; actually, the confetti are tiny male flatweed flowers. In both flatweed and eel grass, the entire male flower is released from beneath the water surface, floats to the top, and in essence becomes the search vehicle. After the male eel grass flower reaches the surface, three tiny stamens become erect and function as a sail. The female flower floats slightly below the surface level, creating a small depression into which the male flowers tumble. In effect, the target is the depression created by surface tension.

In flatweed, the target is the floating cluster of long petals borne by the female flower. The female flower is firmly anchored, however, by a long stalk attached to the base of the plant and rooted into the sandy bottom. Any male flower falling within the petals is completely enveloped as the tide rises, and pollination occurs.

Perhaps the reason that such unusual search vehicles are not found in plants whose pollen is aerially dispersed is the risk of desiccation. The high surface-to-volume ratios of elongated pollen grains might result in rapid, irreversible water loss if the grains were transported through air rather than water. In any case, wind- or animal-dispersed pollen grains are not likely to follow random trajectories. In water, however, the combined actions of wind and orbital wave motion probably introduce enough randomness into the

search paths of pollen to satisfy Koopman's random-search theory.
